# INDEX TO VOLUME CVI.

The Index of the Boston Medical and Surgical Journal is arranged by authors and by subjects. Articles relating to the circulatory, respiratory, or nervous systems are to be found under those heads respectively. This method of indexing is that followed by the Editors of the *Index Medicus*, and is believed to be the most satisfactory plan which can be adopted. F. H. B.

- Adams, Z. B.** Neglect of vaccination, a state vaccine establishment, 111.
- Allen, C. A.** Pelvic hamatocoele, 617.
- Amay (Norwich).** A remarkable case of extremely low temperature, 614.
- Anatomy.** Frozen sections through a thorax with pericardic effusion, 177; recent progress in anatomy, 177; the study of anatomy in the Leipzig University, Walton, G. L., 389.
- Atkins, F. H.** Clon on pulvis after version, decapitation, forepaw, 251.
- Atlee, W. P.** A case of lungeles of the hand cured by scraping with the finger, with some references to the literature of this affection, 289.
- Ayer, J. B.** A severe case of melanoma following pneumonia, 81.
- Baker, W. H.** Recent progress in gynecology, 8; cancer of the uterus, 85.
- Baltimore.** Letter from Baltimore, 491.
- Bancroft, C. P.** Normal cerebellum, following three years of diseased mental action, the mystery of idiocy, 75, 85.
- Barnes, H. J.** The water supply of Boston, 4.

## LECTURES.

### PENNSYLVANIA HOSPITAL.

CLINIC OF J. M. DA COSTA,

*Professor of the Theory and Practice of Medicine and of Clinical Medicine in the Jefferson Medical College, etc.*

#### REMARKS UPON TWO CASES OF LEAD-POISONING EXHIBITING NERVOUS AND MUSCULAR SYMPTOMS.

GENTLEMEN: The two cases now brought before you are very striking ones, each showing marked implication of the muscles, though through different causes. I bring them in together because they both have the same disease.

#### CLINICAL HISTORY OF FIRST CASE.

Andrew M. is forty-two years of age, a house-painter. This man has been working in white lead for thirty-one years and has had frequent attacks of colic. We also learn that these occurred in spite of the fact that he has been in the habit of taking whiskey, as a prophylactic. Notwithstanding the faithful use of his antidote, he has had pains at least a dozen times, so he says, and in referring to them he describes the usual symptoms of lead-poisoning. About a year ago he had a similar attack for which he was treated in this hospital; he went out relieved of his constipation and pain but not entirely well; he states that he was out of sorts for several months. When he returned to his work he followed a branch of the business in which there was no lead used.

#### SYMPTOMATOLOGY; MUSCULAR SPASM; PARALYSIS.

Four months ago, he began again to work in white lead paint, and about three weeks ago he noticed a stiffness or tonic spasm of the muscles of the thumb and fingers which held the brush, in both hands, for he was in the habit of changing the brush from one hand to the other, while painting. This difficulty he found to be greater in the afternoon than in the morning; that is, the stiffness increased when he had been some hours at work. After a few days the loss of power extended from the fingers to the hand, so that he could no longer hold the brush. First, he says there was spasmodic action of the muscles concerned in holding the brush, and afterwards came loss of power; he next noticed that his wrists were weak, and soon he could not hold anything. His bowels were then obstinately constipated, requiring him to employ opening medicine. This shows that muscles in other parts of the body were beginning to be affected, constipation and lead colic being caused by paralysis of the muscular coat of the intestinal tube. During the preceding attacks his gums had been very sore, and the teeth loose. Just before his admission, eight days ago, a similar set of symptoms manifested themselves.

#### NERVOUS PHENOMENA.

Upon entering the ward he was noticed to be, as he still is, pale and weak. He has marked tremor in both his hands, but much more in the left than the right. There is some wrist-drop besides this tremor, the hand hangs down; there is, as you see, also a want of general power in this arm, the hand not only trembles, but he also cannot hold it out except for a very brief period. These are the symptoms he presents now, which were also

noticed upon admission. There is no trembling at present in the muscles at the wrist; he calls our attention, however, to the fact that while there is no persistent tremor, there is an occasional jerk in the muscles, even when the limb is at rest, but as you see, the least effort to use the hand will produce this trembling motion.

#### CONDITION OF MUSCLES, ETC.

Now, gentlemen, I have told you the general history of this case, and I can supplement it by some facts which strengthen his statements. First, let me say, that he has no headache, but has great muscular soreness all over the body, and winces when he is touched as if it hurt him. He actually dreads to be touched. Upon testing the cutaneous sensibility, I find that this is, really, as I have described it to you, a muscular soreness; when I take hold of the skin and pinch it there is no evidence of increased sensibility. He says that he feels it just as anybody would. The muscular soreness is less in the hands, but even in the muscles of the forearm, where as I pinch him, now, there is not much tenderness, as I press deeper pain is evoked. Muscular soreness is then very decidedly present. You see, also, that he is to a certain extent paralyzed, at least muscular movement is very much impaired. He has difficulty in taking off his coat. There is atrophy of the arms, and upon inspection, every now and then I see fibrillary contractions of the muscles, especially around the shoulder. The muscular groups, both flexors and extensors, are wasted. Atrophy of all the muscles of the arm and forearm co-exists, therefore, with this muscular soreness; this in both arms. The muscles of the hand, especially of the ball of the thumb, are deficient; while markedly sensitive they are decidedly atrophied; the interossei are less so.

He never has had headache nor giddiness; but he sleeps poorly, he says he has bad nights, and thinks that it is the pain that prevents him from sleeping. His vision is good, except that the left eye was injured by an accident some years ago. His appetite is very good, and he digests the food he takes. The bowels are opened by medicine, the salines being sufficient to keep them in a soluble condition. His tongue is white, flabby, and tremulous. He has a most thoroughly characteristic blue line on the gums; nor is the blue line confined to the teeth where it is partially obscured by the tartar, but you see a blue stain upon the lower lip upon its mucous surface. His breath, moreover, is very offensive, and the gums are spongy. He thinks himself that this condition was due to some mercury which he had taken as a purgative, but the evidence on this point is very doubtful. Indeed, the resident physician tells me that a good deal that he said when he came in about mercury and the like, was due to hallucination. The man since has been found to be subject to hallucinations.

The urine has been free from albumen; the quantity and appearance are normal. The body temperature is not elevated. Pulse is feeble and compressible, and the action of the heart distinct; the second sound is not quite so sharp as in health, the first is of normal volume.

#### REACTION TO ELECTRICITY.

Now, gentlemen, it is very evident what is the matter with this man; it is a case of most aggravated lead-poisoning with all the peculiar muscular and nervous symptoms characteristic of lead. I will finish our clinical record of the case by testing the condition of the

<sup>1</sup> Reported for the Boston Medical and Surgical Journal.

muscles with the battery; and I might add to our former observations that the muscles of the lower extremity also appear wasted as they are also sore to the touch. What do we find to be the electrical reaction? There is unusual amount of insusceptibility to the action of the faradic current; the muscles barely move under a strong current, while you perceive that it hurts him. That is in the extensor group of the left forearm. Now we are trying the biceps, which contracts a little better. It is very clear that the electro-muscular sensibility and contractility are better preserved in the biceps than in the extensor groups of arm and forearm. The right is similarly affected, but less than the left. Under a strong current the flexors of the right arm also move better than the extensors. Therefore, while the muscular contractility in the upper extremities is everywhere diminished, this is true to a less degree in the flexors than in the extensors. The same reduction of muscular action under the faradic current exists in the lower limbs, though it is nowhere completely abolished.

#### CLINICAL HISTORY OF SECOND CASE; EXAMINATION.

Let us now investigate case two, which is also one of lead-paralysis: William D., forty-one years of age. He has been a house-painter for sixteen years but never had lead colic until two years ago, but he has had it each summer since then. He is temperate. He noticed that he had lost some power in his hands last summer, and three months later he had to give up work on account of inability to use his hands. His bowels were constipated, his appetite good; upon admission he had most marked wrist-drop in both arms, more so than in the other case. He also showed atrophy, and general, though not complete, loss of power in his limbs. Notice the atrophy; there is also characteristic wrist-drop and with it wasting of the muscles, particularly of the forearm. The muscles of the ball of the thumb are almost gone, there is scarcely anything of the thenar eminence left in this hand, but there is a little more in the right; the interossei muscles do not seem to be very much affected. Muscular soreness there is none. The case differs from the preceding one also in the fact that there is no wasting of the lower extremities, which are well developed. He can kick vigorously. He says, however, that he had some loss of power in the lower limbs, though of late they have been much better; it now no longer exists. You can see the difficulty he has in making motions of the forearm, the extensor group of muscles is especially implicated. Let us look at his gums. There is a most marked blue line. He thinks that he has never had fetor of the breath; and he has no nervous symptoms; no headache, nor hallucinations, as in the man we just saw; nor is there any tremor, and he informs us that he has never observed muscular twitching.

We will now also test him with the battery. With a very strong current the extensor muscles contract, the electro-muscular sensibility seems well preserved, though he has no power in the extensor muscles, and even with a strong current we cannot make the wrist bend backwards. In the biceps the muscular contraction is good, very different from the extensor group, and in the flexors of the forearm it is good, slightly impaired as compared with the normal, but still very fair.

#### SUMMARY OF TREATMENT.

You have now seen these two instructive cases; I will indicate their treatment, reserving some remarks

upon it until afterwards. This man is employing the battery, daily, with the faradic current, on the muscles of the forearm, particularly the extensors. He is also using the iodide of potassium (ten grains thrice daily), and has been purged with sulphate of magnesia. He has also been taking strychnia now for about a week, and has already commenced to improve. He takes a thirtieth of a grain three times daily. There has been no evidence of lead in the urine, although we sometimes do find lead discharged by the kidneys after giving iodide of potassium.

The former case is also taking the iodide (ten grains three times a day), and a saline purge; he has not taken strychnia. What shall be done for the muscular pain and restlessness? I will order—

|                        |           |
|------------------------|-----------|
| ℞ Chloral. hydrat.     | gr. xv.   |
| Tinct. cannab. indicæ. | gtt. v.   |
| Syrup. tulatani        |           |
| Aque                   | aa 3j. M. |

To be taken each night, and repeated if necessary. We will not begin the battery with him for the present until we see how the muscular soreness is influenced. He shall be kept upon the potassium iodide, and occasional purges of Epsom salt.

These two cases of lead-poisoning, in one affecting principally the nervous, in the other the muscular, system, are of more than usual interest, and more than usual gravity; they present the typical symptoms about as well marked as you will ever see them. As we have considered their clinical history, and examined them fully, let us now take up the prognosis and treatment.

#### PROGNOSIS.

The prognosis in both, I think, is favorable; I believe, that both, if treatment be continued, will recover. In case number one with the great disturbance of the nervous system, hallucinations, restlessness, tremor, and muscular soreness in addition to the paralysis and atrophy, I think that a longer time will elapse before perfect recovery than in case number two; still, here, too, recovery will finally take place, and in the short time he has been in the hospital a marked amelioration is noticeable in the phenomena; although the gain in power is decided, yet he still exhibits the curious muscular trembling. His digestion is better, the bowels regular.<sup>1</sup> This case did receive some treatment prior to coming into the hospital, but in case two I do not think that there was any particular treatment, at least what it was he does not exactly know.

#### DISCUSSION OF TREATMENT.

Let us inquire into the principles of our treatment, and explain why we use certain remedies in preference to others. Both patients are taking iodide of potassium. In other respects their treatment is quite different except that both take sulphate of magnesia as a purgative. Let us first consider the points in treatment that both have in common: the iodide of potassium and a saline each morning. The reason for exhibiting the former is that this is the most powerful agent that we have to eliminate lead from the tissues; a double decomposition is said to occur, and the iodide of lead is discharged in soluble form. But it is not merely for its chemical effects upon the lead that it is so valuable, but also for its influence upon general

<sup>1</sup> A week later the muscular soreness was much diminished, he slept well, and had no hallucinations. The general improvement was marked. — KEE.

nutrition, for correcting the process of degeneration in the muscles, and removing the stiffness and soreness caused by the lead. For these reasons we find iodide of potassium valuable in other forms of metallic poisoning, even in chronic poisoning by arsenic. Whatever be the *rationale* by which it acts, it does more good than any other therapeutic agent in chronic lead-poisoning. With this view I have placed both cases upon it, and they have responded in a marked manner. That is one point they have in common. Secondly, they have in common the use of salines, sulphate of magnesia. This is indicated because in all cases of chronic lead-poisoning there is torpor of the bowels, and constipation; frequently, in grave cases, there is lead colic, and these were no exception to this general rule: one had repeated attacks, and the other had an attack while in the ward. Then, I say, the object of treatment is to keep the bowels soluble; and to overcome the constipation purgatives generally are necessary. For a long time the sulphate of magnesia has been especially valued in this connection, it has, indeed, a popular reputation as a remedy for lead colic. Whether on account of the sulphuric acid which it contains or not, it has undoubtedly good effects, and has advantages over other popular laxatives in use. At La Charité Hospital in Paris, it was regarded not merely as a laxative but also as an important agent in aiding to eliminate the lead from the system.

Now we will take up the points of treatment in which the cases differ. Chloral, at night, in case number one, on account of the state of his nervous system, his restlessness, hallucinations, and pain, which prevented him from sleeping. Partly, then, to procure rest, and partly for its effect upon the nervous system, we gave the hypnotic. In cases like number two, where the difficulty seemed more localized than in the other, where we have more wrist-drop, I rely more upon galvanism and strychnia. Now, strychnia is a particularly advantageous remedy in cases of lead poisoning, especially long-standing cases in which there exists more decided paralysis or wrist-drop. It is a remedy, I think, which has been far too much neglected. I have read somewhere of strychnia being given in as high as grain doses in lead poisoning. I confess that I was incredulous about it, but when I reflect that when the system is under the influence of one poison it takes correspondingly large doses of another poison to affect it, I am willing to maintain that if only well borne, large doses may do a great deal of good. The strychnia has been supplemented by the battery, but the strychnia does as much good as the electricity. I generally order the strychnia in granules, commencing with a thirtieth, but I have more confidence in the hypodermic use in these cases, using at first one half this dose. In these old cases the strychnia, hypodermically, does more good than when given internally. Where the paralytic affection is localized the battery is of the greatest possible use; where the disorder is general, as in case one, it is of little benefit. There is a belief that you sometimes get results from the continuous current that you cannot obtain from the faradic current, and in obstinate cases I would advise you to try both. Sometimes the muscles will react to the continuous current when they will not to the interrupted, especially when the system is under the influence of lead. It has therefore been asserted that it should be used more frequently than the latter, but where, as in the present case, the muscles react to

the faradic current, and the patient is still improving, I can see no reason for changing it.

#### PROPHYLAXIS.

With these remarks I intended to conclude our consideration of these cases, but one other point occurs to me. Suppose these men go away from here to return to their business, can we give them anything to prevent subsequent attacks? Nothing that I know of will avail except perfect cleanliness. The skin should be kept perfectly clean by a bath at the close of the day. They should live in the open air, do their work in a well-ventilated room, and stop work as soon as "the gripes" appear. It is claimed that sulphuric acid will prevent lead poisoning, and in white lead manufactories they sometimes give the workmen sulphuric acid lemonade. In practice, however, this does not so happen; indeed, sulphate of lead itself has caused lead poisoning. In point of fact, in many white lead works the use of this acid has been stopped on account of its not proving efficient. When the system is saturated with lead vapor baths may aid in getting rid of some of it through the skin by encouraging perspiration, but the essential part of the prophylaxis in a person very susceptible to the poison is to escape from the influence of the lead by a change in the occupation or surroundings.

#### IN WHAT CASES SHALL THE MEDICAL EXAMINER DECLINE TO VIEW A DEAD BODY? <sup>1</sup>

BY MEDICAL EXAMINER ALFRED HOSMER, M. D., OF WATERTOWN.

THE medical examiner forms a conspicuous and important element in that vast system of protection which it has been found necessary to establish for the community. In one of his relations to the public he is, but in no mental sense, a servant, and as such he should be willing, prompt, and obedient. With this idea in mind I have never failed to report for duty whenever a requisition has been made for my official services. Yet it has sometimes happened that after reaching the place where immediate action on my part was expected, I have been forced to the conclusion that the case in hand not being among those contemplated and provided for by the statute of 1877, I had derived no authority from that act to take cognizance of it, and have therefore declined to hold a view in the legal sense of the phrase.

For instance, one morning a police officer requested me to give immediate attention to a case which had occurred five miles away, in the district of Medical Examiner —, then absent. At much personal inconvenience I responded to the summons without delay. I found in the custody of the undertaker the body of an elderly man, who, early in the day, while in company with a friend, had died suddenly in the street. Careful interrogation failed to discover any suspicion that the death was not a natural one, and also elicited the statement that the deceased had recently consulted a neighboring physician. The fact that the death had been both public and sudden was assigned as the only reason for calling a medical examiner. Yet a little reflection will satisfy all that neither of these features in that case could be considered *per se* as proof of

<sup>1</sup> Read before the Massachusetts Medico-Legal Society.

"death by violence." Sudden deaths from natural causes are unquestioned, although their frequency has not yet been exactly determined. Their origin and relations form a subject which deserves a full elucidation before this Society. Public deaths are not likely to be unnatural ones unless they occur under circumstances which plainly show their violent character. There can be no doubt as to the nature of the fatal results that follow a social disturbance, which may exist in any and all degrees, from a simple individual assault to a riot of the largest proportions. There is no difference of opinion as to the kind of death which overtakes the victims of a disaster or awaits those who lose their lives through that agency which, with a careless freedom of language, we are accustomed to speak of as accident.

To return to the point whence this digression started, I sought the physician who had attended the deceased. On the demand of the instant he could not furnish the information I desired. He promised to investigate and report; in a very short time he wrote to me as follows: "Mr. — had a marked stenosis of the mitral valve; was moderately comfortable with care. I learn that he had been drinking hard a day or two preceding his death." Such evidence as this fully confirmed me as to the correctness of the conclusion at which I had arrived, and upon which I had acted, when, in the presence of the dead body, I had expressed the opinion that the case did not come within the province of the medical examiner. There was no duty prescribed by law that I could perform, there was no service that I was qualified to render, and, rendering none, I considered myself entitled to no compensation, and have never claimed any.

An answer to the question which forms our subject must be obtained from a careful study of the law, of which the seventh section is as follows: "Medical examiners shall make examinations as hereinafter provided upon the view of such persons<sup>1</sup> only as are supposed to have come to their death by violence."

What is a death from violence within the meaning of the statute? In a general statement it is one with the causation of which human agency is connected directly or indirectly: through default of a reasonable and necessary precaution; through neglect to secure protection against danger known to exist or to be incurred; through force, mental, mechanical, medicinal, chemical or toxic, exercised and applied either ignorantly and unconsciously, or under the impulse of excitement, without premeditation or with deliberation and improper purpose. This definition requires some explanation and limitation, and will be better understood if we constantly bear in mind the fact that the high function of the medical examiner is to assist in the detection of *crime against life*. But the location of the line which separates guilt from innocence is fixed by the provisions of statute law. Violence of death has no constant relation to legal prohibition and penalty, and is not confined to the unlawful destruction of life. In deference to the necessity and the right of self-defense the shooting of an unprovoked assailant may receive no sentence of condemnation. Yet such a death must primarily be treated as a violent one, for the true character of the deed can be determined by judicial inquiry alone, and exoneration is attained only with the verdict which concludes the inquest. On the other hand, death by violence cannot

be held to include such human agency as that, for instance, which in the form of parental indiscretion has contributed so freely to the mortality of infants. Neither can it mean those deaths which, also traced to a similar origin through what some one might have done but has failed to do in a preventive sense, are often sudden, always premature, accidental as we call them. The child who, for want of attention, is allowed to be drowned in a cistern or scalded to death in a vessel of hot water; the boy who in his carelessness falls from a tree and breaks his neck; the laborer who in perfect health and in pursuit of his daily work receives a heavy blow upon the abdomen, and three days later suddenly passes into a collapse from which he never rallies; the man of business who with hasty and unguarded steps collides with a post in the street and sustains injuries which are ultimately fatal; the victim of melancholy who wanders from home and is lost, and whose remains are found months afterwards with everything untouched except by the process of decay; those who perish by the unmistakable consequences of great natural commotions, such as thunderstorms and tornadoes; not one of these furnishes an example of death by violence in the medical examiner's sense; no one of them dies by the method provided in the easy and uninterrupted order of nature; but on the other hand they do not die through an unlawful course of action on the part of any person.

"Supposed to have come to their death by violence." The word "supposed" imparts a degree of elasticity to the section, and without being intended to exclude those cases which derive a known character from obvious violence, enables it to cover a field the contents of which, as being unexplored, would otherwise be uncertain; and in which either the rights of good personal reputation or the demands of justice require that doubts should be replaced with facts. The term in question seems, at first sight, to be a vague one; it implies a mental process, but carries no reference to the conditions which shall render that process a sound and valid one. We must believe that the word is intended to mean the average opinion of intelligent minds whose conclusions, unmixt with the elements of credulity and timidity, represent the preponderance of well-considered testimony. In addition to this, violence may reasonably be "supposed" in those cases which, though not presenting *prima facie* a suspicious aspect, cannot be proved by a very large probability to fall within the range of the operation of the natural causes of death. Whenever violence is not self-evident but only supposed, it is the duty of the medical examiner, before taking any action, to assure himself that the theory of illegal force commands a plausible support. His position is not a judicial one, yet his decisions may be final. He must judge of the applicability of the law to the case in hand. He must exercise that discretion which takes precedence of learning in the enumeration of qualities which determine the selection of candidates for office. Thus will he aid in establishing those principles upon which must be based every rule of official action, and in teaching the public to understand and accept those distinctions which are of fundamental importance, and which cannot be neglected without endangering his own integrity and dignity, and doing injury to the cause of law and order.

To the rule laid down I have in practice made an exception when a notice has been sent by a magistrate or municipal officer of high grade. I have then en-

<sup>1</sup> The italics form no part of the original law.

tered upon a medical examination without preliminary questions, and it is a curious fact that in all such instances I have found myself dealing with a kind of inverted cone, so that the further down the investigation proceeded the nearer it has come to nothing.

"Upon the view of the dead bodies of such persons only as are supposed" etc. The word "only" is here used in a strong restrictive sense, and contains the prohibition which limits the official competence and jurisdiction of the medical examiner. Unless there be a supposition of violence his commission confers upon him no authority and he is powerless.

In deciding what is the significance of the word "persons," I shall take the liberty of referring you to an instructive paper,<sup>1</sup> written in answer to the question "What constitutes the dead body of a person?" and presented to this Society at the February meeting. The conclusions to which the writer came, after careful study and consultation, interest us now only so far as they relate to what of humanity is not included in the definition of "persons," as that term is understood and accepted by those who interpret law, and explain the intent of its equivocal portions. According to the indisputable authorities whom he quotes, judicial voices all agree in the declaration that a child is not born until it is entirely extruded from the maternal body, and that, although it may have breathed at some point in the parturient passage, if it be still at the instant of complete expulsion it has never become a person; and, therefore, cannot have been the subject of such violence as the medical examiner is qualified to recognize and certify to. No child known to be dead-born can be inspected in the sense of viewing the dead body of a person. But the question at once arises as to what course the medical examiner shall pursue in the event of the discovery, through the improper disposition of the body of a child born prematurely or at term, respecting which no information can be obtained. For a portion of them, Medical Examiner Holt lays down the following rule: "It would, perhaps, only be safe to conclude that all fetuses born in the first half of pregnancy cannot live for any period, and the body of such an one cannot be considered the dead body of a person within the meaning of the law."

According to Caspar the maximum length of a fetus at the end of the twentieth week of utero-gestation is twenty-eight centimetres. The application of a metric measure will determine with sufficient accuracy whether in a particular instance the medical examiner is dealing with a person or a thing. In other words he must decline to view a fetal body unless it be more than twenty-eight centimetres long.

It appears from the report of the Executive Board for 1879<sup>2</sup> that in thirty-eight per cent. of all the views held the cause of death was found to be a natural one. Where three succumbed to violence, two yielded to nature. Can it be that in so large a proportion of the cases there was so much obscurity and mystery as to justify excite a suspicion of unlawful agency? Is it not possible that the office of medical examiner, like the drug last added to the *materia medica*, has been perverted through its application to conditions for which it was never intended? If this mistake has been committed, there was during the first few months that followed his institution an apology for the deficient

condition of our statutes. An act<sup>3</sup> of the legislature of 1878 is the first that has ever authorized any one to certify to the cause of death whenever there has been no medical attendant during the last illness. Having made a general provision, it excepts cases of violence, and refers them to the medical examiner for certification. It thereby intimates that the simple fact that a man has died without medical supervision is not a sufficient reason for demanding a view; that it does not require or even permit the medical examiner to hold one.

"But nothing herein shall prevent any medical examiner from acting as such in any part of his county." This provision forms the concluding portion of the sixth section of the law to which we owe our official being. It is simply a negation, and conveys the idea that the medical examiner has full legal liberty to exercise his office throughout his county irrespective of the district lines originally established by commissioners. Without violating any statute a physician may render professional service to every patient who seeks it, yet there is a rule of etiquette, dictated by the sentiments of honor, justice, and propriety, not to speak of the less worthy consideration of self-protection, which restrains the average medical man, and admonishes him not to interfere in work already assigned to another. This principle should guide the medical examiner in his conduct towards official neighbors. Human nature is tenacious of its lawful possessions, it is jealous and intolerant of seeming intrusion. Provoke collision and coöperation is at an end. The success of this new system will not attain the highest possible degree unless its essential instruments act in cordial harmony. We can give no better proof of our devotion to the cause which we have espoused, and to which the acceptance of our commissions has committed us, than by cultivating and maintaining among ourselves relations, not simply of mutual good-will and confidence, but of active friendship. We should adopt a policy which is rendered safe and simple by the exclusion of all doubts and questions as to propriety. Therefore I hold the opinion that a medical examiner should decline to hold a view outside of the district for which he has been appointed unless the medical examiner whose district he enters either requests to be relieved from duty in a particular instance, or is so situated that his services cannot be obtained within a period of time which is reasonable when considered with reference to the necessities of a given case.

Practice is the acknowledged route to perfection,

<sup>3</sup> ACTS OF 1878, CHAPTER 174. SECT. 1. No human body shall be buried, or removed from any city or town, until a proper certificate has been given by the clerk of local registrar of statistics to the undertaker or sexton, or person performing the burial, or removing the body. This certificate shall state that the facts required by chapter twenty-one of the General Statutes have been returned and recorded; and no clerk or local registrar shall give such certificate or burial permit until the certificate of the cause of death has been obtained from the physician, if any, in attendance at the last sickness of the deceased, and placed in the hands of said clerk or local registrar; *provided*, that in those cities and towns where local boards of health have been established, the certificate of the cause of death shall be approved by such board before a permit to bury is given by the registrar or clerk. Upon application, the chairman of the local board of health or any physician employed by any city or town for such purpose, shall sign the certificate of the cause of death to the best of his knowledge and belief, if there has been no physician in attendance. He shall also sign such certificate, upon application, in case of death by dangerous contagious disease, or in any other event when the certificate of the attending physician cannot for good and sufficient reasons be early enough obtained. In case of death by violence, the medical examiner attending shall furnish the requisite medical certificate. Any person violating the provisions of this section shall be punished by a fine not exceeding twenty-five dollars.

<sup>1</sup> Boston Medical and Surgical Journal, vol. ciii., p. 200.

<sup>2</sup> Boston Medical and Surgical Journal, vol. ciii., p. 265.

and the novitiate is terminated only by the exercise and action which constitute experience, and confer new ability. For his training and instruction, for the gratification of that sense which appreciates and enjoys the curious and the interesting, the medical examiner needs all the opportunity and all the material which his district can possibly furnish. He is defrauded and retarded in his official growth whenever that to which he alone has a claim is converted to the use and advantage of another.

The medical examiner, required to be "learned in the science of medicine," must be a physician, and is under a double obligation to be of good repute. Even if his ideas of duty are less severe than those which have found expression here, his conduct should be regulated by those principles, a strict adherence to which has made the name of medicine so suggestive of intelligence, moral worth, and public spirit.

### MOSES AS A SANITARIAN.<sup>1</sup>

BY EDWARD T. WILLIAMS, M. D.

UNDERSTANDING that a paper on circumcision was to be read at the present meeting, it occurred to me that a few brief remarks on the sanitary regulations of the ancient Hebrews might be not inappropriate. It is true I can say nothing but what every one can read for himself in the Bible, yet there may be some to whom a brief review of the subject from a medical standpoint will be interesting.

In the first place, as to the authorship of the Mosaic books, Deuteronomy (chap. xxxi.) states that Moses wrote a book of the law, and gave it to the priests, the sons of Levi, to put into the ark with the two tables of stone containing the ten commandments, and commanded that it should be publicly read every seventh year in the presence of all the people. In Joshua (chap. viii.), after the occupation of the promised land, we learn that the book was so read before all Israel by Joshua, and that a copy of it was written upon stone at the altar near Bethel by the same hand. Joshua xvii. 1 states that the whole congregation of Israel afterwards assembled together at Shiloh, and set up there the tabernacle which contained the ark, and without doubt, also, the sacred book. At any rate the book was certainly preserved, for Joshua, in his old age, twice more assembled the people together (chaps. xxiii. and xxiv.), solemnly warned them to keep and to do all that is written in the book of Moses, and also added certain words to the book. In the time of Eli, three or four hundred years after, the tabernacle and ark (1 Sam. i., ii., iii., iv.) were still at Shiloh, which had during the whole period of the judges been a place of yearly resort by the pious Israelites (Judges xxi. 19; 1 Sam. i. 3). There can be little doubt that the sacred records were there too. Shortly before Eli's death the ark was removed from the tabernacle, and subsequently captured by the Philistines. The tabernacle remained at Shiloh under the charge of the priests, and was afterwards removed to Gibeon, a place nearer Jerusalem (1 Chron. xvi. 39; 1 Chron. xxi. 29; 2 Chron. i. 3), from which it was again removed by Solomon and deposited in the temple (1 Kings viii. 4; 2 Chron. v. 5). There is no direct mention of the

books. A brazen altar, however, made under the direction of Moses by Bezaleel, the son of 'Uri, was preserved with the tabernacle at Gibeon (2 Chron. i. 5). The brazen serpent, made by Moses in the wilderness, was also preserved somewhere, probably at Gibeon, for we read (2 Kings xviii. 4) that it was purposely destroyed three hundred years after by Hezekiah. The two tables of stone were found unmolested in the ark by Solomon (1 Kings viii. 9; 2 Chron. v. 10). Is it not reasonable to suppose that the sacred books would have been guarded with equal care, and must, therefore, have been in existence at the same time? At any rate they did exist under Jehoshaphat, fourth in descent from Solomon, for he sent priests through the cities of Judah with the book of the law in their hands to teach the people (2 Chron. xvii. 9), and again, under Josiah, the same book was found in the temple by the high priest, and publicly read at the great feast of the passover (2 Chron. xxxiv. 14, 30). It was known and read by Daniel during the Babylonish captivity (Dan. ix. 13), as were also the writings of Jeremiah (Dan. ix. 2). Ezekiel (Ezek. xiv. 14) speaks familiarly of Noah and of Job. Facts which show that numerous books and probably numerous copies of them still survived. In what manner the Psalms were preserved is plainly shown in Psalm cxxxvii. How absurd, then, the idea of some skeptics that the Pentateuch was composed by Ezra, who simply carried back from Babylon at the restoration the book of the law in which he was accomplished and "ready scribe" (Ezra vii. 6, 14). From this period its history is sufficiently well known, and though there can be no doubt to the critical mind that the book as originally written has undergone alteration, revision, and interpolation, the probability certainly is that a considerable portion of it was really written by Moses himself.

How far the system of Moses was original with himself no one can say. He certainly borrowed largely from the Egyptians, as archaeology shows, a fact which strikingly corroborates the Scriptural account of his early education, and the broad historic fact of the Exodus. But from whatever source the fragments of his system may have been derived the system was his own and the Power's which guided him.

So far as we know Moses was the creator of preventive medicine, an idea thought to be peculiarly modern. We know little of the treatment of the sick as pursued by the ancient Jews. The references even to physicians as a distinct class are rare in the Old Testament. But the idea of a sound mind in a sound body, the value of physical health to the state and the individual, were profoundly felt by the Jews. The notion of promoting health by preventing themselves from becoming sick was the foundation stone of their sanitary legislation.

The foremost subject of their code was dietetics. The Jews were good feeders. They were rich in sheep and cattle, and partook liberally of fresh meat. It has been said that the greatness of England is founded on beef and beer. Undoubtedly that of the Jews was partly due to a plentiful supply of meat. The flesh of reptiles, however, of all carnivorous animals, and of swine was condemned as unclean (Lev. xi.). So also, the flesh of diseased animals or those which died a natural death. The prohibition against pork, considering the heat of the climate and its liability to be diseased, must be considered as a safe, if not absolutely

<sup>1</sup> Read before the Norfolk District Medical Society, November 29, 1881, and printed by request of the Society.

necessary provision. It was left for the youngest of the sciences, histology, through the discovery of the trichina, to fully expose to the modern world the transcendent wisdom of the Hebrew lawgiver on this point.

The laws concerning "issues" or discharges from the genital organs, both of men and women, display a similar wisdom. The word "issue" seems to be used indifferently for discharges of blood, pus, or mucus. The dangerous character of all such discharges was fully understood, and but little attempt was made to discriminate between them. All persons so affected were declared "unclean" (Lev. xv.) They were obliged to live apart, and abstain from sexual intercourse. Their clothes, bedding, and cooking utensils were also declared "unclean." Any person even touching them was obliged to wash carefully his body and his clothes. This *régime* was continued for seven days after the cessation of all discharge, after which a thorough ablution of both person and clothing was necessary before the affected individual could resume his place in society. With women after childbirth from one to two months of isolation were required. It is easy to see that these rules if faithfully carried out would be an efficient preventive of gonorrhœa. Yet we, in our enlightened age and country, dare not legislate on the subject of venereal disease, blindly refusing the protection of the law not only to the guilty victims of illicit pleasure, but to great numbers of innocent men, women, and children, who have to suffer and often to die for the faults of others. Leaving wholly out of view the humane aspect of the question, the mere pecuniary loss to the State from such defective legislation is incalculable.

The nature of the tsaraath or Mosaic leprosy has been much disputed. That it was something quite different from the Grecian elephantiasis, commonly called leprosy, of the present day is clear enough from the description given (Lev. xiii., xiv.), and from the fact of its attacking articles of wearing apparel, whether of wool, linen, or skin, and even the walls of houses. Nothing but some species of *vegetable mould* or *parasite* could possibly produce such an effect. It affected by preference the hairy parts of the body, like favus, and, like favus, caused the diseased surfaces to turn white. It also affected the hairs, like favus, causing them to turn white or yellow and thin. This affection of the hairs was the crucial test by which the priestly physician was to decide the true character of the disease, as it still is the chief point of diagnosis with all parasitic affections of the hair. It was also excessively contagious, so that it seems pretty clear that the disease must have been some species of vegetable parasite, and may possibly have been favus.

The laws concerning this disease were most strict. Every person having a suspicious eruption on his body was obliged to present himself to the priest for inspection. If it proved to be leprosy he had his clothes torn and his upper lip covered in some way to make him conspicuous, and was turned outside the camp, where he was compelled to live alone until cured. If the diagnosis was doubtful he was shut up a week or a fortnight and then reexamined. If the leprosy had not declared itself by this time he was discharged; another fact which goes to show that the disease was one of rapid progress, like a parasitic disease, and not a chronic one like elephantiasis.

Articles of clothing attacked by leprosy had also to

be submitted to the priest. If found diseased they were burnt forthwith. If doubtful they were washed, and reexamined at the end of a week, when they were either burnt or pronounced clean.

When the walls of a house were attacked the parts affected had to be torn down and carried to a refuse heap outside the city. The remainder of the wall was thoroughly scraped, the scrapings themselves being carried out of the city, and the broken places rebuilt with fresh materials. If these means proved insufficient the whole house was demolished and the *débris* removed from the town.

Modern science may have discovered simpler methods of disinfection, but certainly nothing more thorough or effective.

It remains to speak of circumcision. The origin of this rite is doubtful. It was certainly practiced by the Egyptians, but whether before the time of Abraham or not is perhaps difficult to say. According to the Bible account it was not adopted by Abraham till some time after his residence in Egypt, and may therefore have been borrowed from Egyptian usage, a notion which nowise conflicts with the statement that it was enjoined upon Abraham and his descendants by divine command. It does not appear to have been too faithfully carried out even under Moses, who, it would seem from Exodus iv. 25, even neglected to circumcise his own son, till Zipporah, his wife, thoughtfully rectified the omission. Again, it is stated in Joshua v. 2-5, that none of the Israelites who were born in the wilderness during the forty years' wandering had been circumcised, though their fathers who came out of Egypt had been. For this reason Joshua, as soon as he had crossed the Jordan, made a halt and consummated the rite upon all the people at Gilgal. The law ordained that it should be practiced upon every male child on the eighth day after birth (Lev. xii. 3).

The object of this singular rite is nowhere stated in the Bible. It probably does good in several ways.

First, the exposure of the glans penis to the air and to friction from the clothes dries and hardens its surface and renders it less liable to abrasion in sexual intercourse, and consequently to venereal ulcers. It is known that Jews rarely have syphilis, though it is an open question whether this disease prevailed among the ancients. It may perhaps have been included under those plagues of Egypt, the "botch," the "emerods," and the "scab" (Deut. xxviii. 27), with which Moses threatened the Israelites as a punishment for disobedience to the divine command. At any rate soft chancres must have been well known. I find proof of this in the account given, in 1 Samuel v., of the plague of "emerods" which occurred among the Philistines of Samuel's time after their capture of the sacred ark. These "emerods" (a corruption for hæmorrhoids) affected the "men of the city, both small and great, in their secret parts," and caused great destruction of life. The word "emerods" is certainly a mis-translation, for the description given bears no resemblance to the disease now known as hæmorrhoids or piles. If the account is true, it could hardly have been anything else than some severe species of phagedænic chancre, like the famous "black lion" of Portugal, or the "Chinese pox" familiar to Pacific Ocean sailors. Such epidemics would be largely prevented by the general adoption of circumcision.

Second, the removal of the foreskin is acknowledged to be useful as a preventive of masturbation. It not only

renders the act itself more difficult, but by diminishing the sensibility of the part and favoring the removal of irritating secretions diminishes also the propensity to the act. It is certain that this vice is a prolific cause of nervous diseases and even of insanity among Christian nations. Its effects in this direction may have been overstated by some writers, yet it is undeniably true that it often does produce the most serious results. The habit itself when fully formed, and a species of paralysis resulting from it, have in numerous instances been cured by circumcision. Hence one of the strongest arguments in its favor.

Third, it prevents the accidents of phymosis and paraphimosis, with their train of evils. Among these may be reckoned cancer, which is stated to be peculiarly common in persons affected with phymosis.

Fourth, it prevents the retention of the sebaceous secretion, and the ensuing balanitis to which many persons are subject.

Lastly, it probably promotes continence by diminishing the pruriency of the sexual appetite. It might naturally be expected that the removal of a portion of the prepuce with its sensitive nervous filaments, the blunted sensibility of the parts remaining, and their free exposure to cold air, might tend to produce this result without in the least impairing the virile power of the individual. It might further be expected to strengthen the general, and especially the nervous, system, by removing those sources of irritation which by sympathy and reflex action so often act unfavorably upon it. That it really does produce these effects is a matter of wide-spread belief. The remarkable exemption of the Jews from insanity and nervous diseases, even their general good health and longevity, may in no small degree be attributable to these causes. At any rate it is a fact that the Jews are the healthiest race in existence. They have produced the greatest men, and contributed more to the advancement of civilization than any nation known to history. However degenerate, morally speaking, some of their modern descendants may be, they certainly have not degenerated physically, a sufficient answer to the often repeated assertion that civilization tends to physical weakness, for the Jews have been longer civilized than any other highly civilized people. May we not then venture the inference that the rite of Abraham, or Moses, has had its share, and possibly a very important share, in the production of these wonderful results, and that it might perhaps be profitably imitated by other nations?

The above is a brief summary of the most important sanitary provisions of the Mosaic code. Proud as we are of the great discoveries of modern science we cannot repress a feeling of wonder at the astonishing wisdom of these old laws. We find in them much that we ourselves might advantageously copy. We are far too apt to forget the greatness of former ages in our boastful praises of the times in which we live. It is good for us to turn back now and then to cull a lesson from the past, and do reverence to the memory of the mighty dead.

—The physicians of Copenhagen lately held a meeting, when a resolution was adopted approving the proposal to hold the next International Medical Congress, in 1884, at their city, and pledging their cordial welcome and hospitality to the Congress.

## RECENT PROGRESS IN GYNÆCOLOGY.

BY W. H. BAKER, M. D.

### TREATMENT OF UTERINE FLEXIONS.<sup>1</sup>

The author agrees with Dr. Hewitt that, in cases of acquired flexion, an unhealthy condition of the uterine tissues, "undue softness," connected probably in a large proportion of them with general malnutrition, is the condition antecedent to the bend, and he thinks a recognition of this to be primarily important in the treatment. The necessity for treatment depends rather upon the amount of obstruction occasioned by the flexion than upon the amount or form of the flexion itself. In cases of retroflexion, if there be no exudation or active inflammatory action present, he would replace at once and adjust a pessary, even if endometritis exist, which he has found to disappear gradually as the uterus is kept in a normal position. In cases of antelexion uncomplicated, he advises the frequent careful passing of graduated bougies during the intermenstrual period, not using them, however, within ten days of an expected menstruation.

### LACERATION OF THE CERVIX AS COMPARED WITH COMPLETE INTERNAL DIVISION OF THE CERVIX.<sup>2</sup>

In considering the extent of this lesion, which is followed by changes requiring, sooner or later, treatment by surgical interference, the author advances the statement which we have so often insisted upon, namely, it is only when the laceration is lateral and extends beyond the crown of the cervix upon one or both sides that evil consequences follow. Among the factors which derange the circulation of the uterus while undergoing involution, he gives prominence to open lacerated wounds of the cervix extending entirely through the cervical wall. He shows how the lips of the cervix are forced apart by the superincumbent pressure, the womb finally resting upon the inner surfaces of the everted lips. This gives rise to influences which bring about ulceration and areolar hyperplasia. No such conditions or influences are present in the division of the cervix, for then the uterine structure is healthy, the weight of the uterus is not increased, and the constant tendency of the divided surface is to unite by first intention. It is often with the greatest difficulty, in fact, that such union is prevented. The author concludes as follows:—

I. Parturient laceration of the cervix occurs in a womb whose tissues are in a state of fatty degeneration, and therefore have no tendency to heal.

Division of the cervix is performed upon a womb whose tissues are in a perfectly normal state, with an almost insuperable tendency to heal.

II. Parturient laceration interferes with a physiological function of the womb, namely, the process of involution.

Division of the cervix interferes with no function of the womb, but on the contrary facilitates the performance of one of its most important functions.

III. Parturient laceration occurs at a time when the weight of the womb is so great as to force the divided lips apart by pressure against the posterior vaginal wall, and so to prevent healing.

Division of the cervix is performed while the womb

<sup>2</sup> By Virgil O. Haddon, M. D., American Journal of Obstetrics, July, 1881.

is normal in weight, and therefore the divided surfaces remain in apposition, and will heal as far as they are allowed to by the physician.

IV. Clinical experience shows that parturient laceration is productive of a long train of distressing symptoms.

Clinical experience shows that division of the cervix produces no injurious effects if properly done; but, on the contrary, completely and permanently relieves a very painful and persistent disease.

#### INFLAMMATION OF SKENE'S DUCTS AS A CAUSE OF VAGINISMUS.<sup>1</sup>

Dr. Skene calls attention to a case in his practice where inflammation of the two small ducts on each side of the meatus urinarius was the cause of vaginismus, which yielded to simply slitting open the ducts from within outwards, and applying a bit of cotton wet with iron to prevent them from uniting.

#### REMOVAL OF THE UTERINE APPENDAGES.<sup>2</sup>

The author reports an oöphorectomy. The patient was one for whom he had previously aspirated, by the vagina, an abscess of the right ovary, evidently occasioned by a sponge tent left for nine days in the uterine canal. Two years had elapsed since the aspiration, when, among other symptoms, the rise of temperature at night and the night sweats led him to suspect the presence of pus somewhere about the pelvis, although no fluctuation could be detected. An exploratory incision was therefore made through the abdomen, and the pelvis was found roofed over by adherent coils of intestines, which were lifted with much trouble. Below these the whole of the organs were matted together, and their identification was a matter of the greatest difficulty. He finally succeeded in recognizing the right Fallopian tube, distended into a cyst, with greatly thickened walls, and full of pus. Below it and immediately adherent to it lay the ovary, as large as an orange, and containing some old cheesy matter,—the remains, probably, of the abscess tapped more than two years before. The uterus was bound down in the cul-de-sac by old adhesions, and from these he relieved it. He found the left ovary adherent below the fundus, and from it the left Fallopian tube ran a circuitous course, like a sausage in appearance, and adherent to the brim of the pelvis, the uterus, and a piece of small intestine. It contained about two ounces of pus. Both ovaries and tubes were removed, the latter being cut off close to their uterine attachments. The hemorrhage during the operation was very troublesome, but was controlled by sponge pressure. The patient recovered without a bad symptom, and is perfectly free from pain for the first time since the incident of the sponge tent. The uterus is perfectly free, and any movement of it gives no pain.

If cases with so extensive adhesions can be successfully operated upon, it certainly opens a new field for the treatment of many of those hitherto regarded as most intractable.

#### "ON REMOVAL OF UTERINE APPENDAGES FOR THE ARREST OF UTERINE HÆMORRHIAGES."<sup>3</sup>

In a paper read before this Society, the author, Mr.

<sup>1</sup> Transactions of the Obstetrical Society of New York, American Journal of Obstetrics, July, 1881.

<sup>2</sup> By Lawson Tait, F. R. C. S., British Medical Journal, May 14, 1881.

<sup>3</sup> Report of the Royal Medical and Chirurgical Society, London Lancet, May 28, 1881.

Lawson Tait, stated that his experience had shown that the removal of the ovaries was not a certain method of arresting menstruation, while removal of the tubes as well as the ovaries seemed to be so. He cited thirty-one cases, twenty-seven of which recovered from the operation and four resulted fatally. The following conclusions might, he thought, be legitimately drawn from them:—

(1.) So far as its primary results are concerned, removal of the uterine appendages for the arrest of intractable uterine hæmorrhage is an operation quite as easily justified as any of the major operations in surgery.

(2.) So far as its secondary results are yet known, it is an operation which yields abundant encouragement for its further trial.

As a conclusion indicated but not wholly proved, he thought he might formulate a statement that removal of both tubes and ovaries was necessary to the immediate arrest of menstruation.

#### SOUNDING THE URETERS.<sup>4</sup>

In the Gynecological Section of the Congress of Naturalists at Salzburg, Dr. Rawleek describes his new method of sounding the ureters without preparatory operation. The value of determining their position is shown by the frequent wounding and ligating they undergo in laparotomies and in extirpations of the uterus. In the latter operation for carcinoma it is only possible to cut away all suspicious tissue when the position of these canals is known. He therefore looked about for a method simpler than those of Tschann and Simon, and, after long and patient experimentation, he found it. He depends upon the fact that the trigonum is more or less plainly marked out by the folds on the anterior vaginal wall. The woman is placed in the knee-elbow position, and the perineum retracted by Simon's or Sims's speculum. The air fills the vagina and stretches the anterior wall. From the little prominence which ordinarily marks the end of the urethra two sets of folds pass off right and left at an obtuse angle. These are crossed higher up by ridges running laterally. The triangle formed by these ridges corresponds to the trigonum, and the openings of the ureters lie in the direction of these folds. With the sound in the urethra it is possible, by pressing the knob against the vesico-vaginal septum, to follow its movements, and usually it has been easy to find the openings of the ureters in the direction of these folds. A peculiar feeling teaches one after a little experience when one is in the ureter. The author has in this way sounded fifteen women, sometimes easily, sometimes with more difficulty. He avoids passing the sound beyond the point where the ureter bends out of the small into the larger pelvis, because it might be perforated or too much stretched. Practically this method might be of use in stenosis of the ureters when not above the lesser pelvis, and the question whether eclampsia is caused by compression of the ureters might be solved. It might also serve in the diagnosis of one or double sided kidney disease, and in the treatment of diseases of the ureters and pelvis of the kidneys. He cites a case where severe cramps were cured by sounding the ureters. A thick plug of mucus followed the probe from the right side, which had evidently caused retention.

## Hospital Practice and Clinical Memoranda.

### MASSACHUSETTS GENERAL HOSPITAL.

SERVICE OF DR. H. J. BIGELOW.

CASE REPORTED BY DR. WILLIAM D. HODGES.

*Radical Cure, without Operation, of a Large and Inflamed Umbilical Hernia, of Seven Years' Duration, and Irreducible for Two Months before Admission to the Hospital. The Hernia was slowly reduced by Compression with Adhesive Straps, and the Cavity of the Inverted Integuments Obliterated by Blistering during a Period of Six Months.*

Mrs. B., Irish; thirty-two years of age; strong and healthy; weighs two hundred and thirty pounds. Seven years ago, after a third confinement, she discovered a slight swelling at the umbilicus, which increased in size until it became necessary to wear a binder to keep the protrusion in place. During warm weather the patient was in the habit of throwing off this binder, and there followed a constant increase in the size of the swelling. Two weeks before her admission to the hospital the tumor became painful, and its under side was ulcerated from chafing.

November 4, 1880. On admission the tumor was of the size of a child's head, and its whole mass was red and inflamed. Manipulation caused nausea. There had been vomiting for five days before entrance, and no movement of the bowels for three days. After etherization only a small portion of the tumor could be reduced by Dr. Bigelow. The remaining part, which hung down toward the pubes, was then supported by charpie placed beneath it, and compressed and held in position by adhesive plaster. A poultice was applied over all. Temperature 102° F.

November 8th. The hernia was again in part reduced by Dr. Bigelow, causing a slight amount of pain, and the strapping with adhesive plaster was renewed. The tumor was now about the size of a large apple. The bowels spontaneously moved at this time, seven days after the first symptoms of strangulation. Temperature normal.

November 14th. Pressure was applied upon the mass of skin and its contents by means of a large cork with a convex surface held firmly in place by adhesive plaster and a swathe.

November 21st. The integument of the sac was puckered. It was of a dark color, but there was no tenderness or lack of sensation. The discoloration was probably due to ecchymosis from tight strapping. Examination revealed two distinct rings: a large one in the place of the umbilicus, at its side a smaller one which appeared to be directed toward the larger ring.

November 29th. (Twenty-five days after entrance.) The sac has become invaginated, and the depression which occupies its place will hold an ounce and a half of water. The larger ring readily admits the forefinger. There is some tenderness.

December 2. Tincture of Cantharides was injected into the cavity formed by the invagination of the sac, in order to blister the surface and cause its adhesion.

December 18th. Liquor ammoniac (fort.) was injected and allowed to remain for several minutes.

December 26th. Tincture of iodine (one part to eight of water) was injected.

January 3d. The sac has lost its former tendency to protrude when the pad is removed.

January 21st. Considerable suppuration from the invaginated surfaces, and much pain.

February 8th. Liquor ammoniac (fort.) again injected. The invaginated surfaces of integument appear to be growing together.

March 1st. (One hundred and sixteen days after entrance.) Granulations are seen at the neck of the inverted sac.

March 19th. Liquor ammoniac (fort.) injected.

April 13th. Interior of the inversion touched with nitrate of silver. A sinus still admits a probe or port-caustic.

May 15th. A large, tight-fitting truss was applied over the ring.

May 25th. (Two hundred and two days after entrance.) The patient sits up for a short time. There is no tendency in the hernia to protrusion. The cavity formed by the invagination of the sac is entirely obliterated.

June 1st. The patient walks about the ward.

June 6th. (Two hundred and fourteen days after entrance.) Discharged well, although directed to wear the truss at present as a matter of precaution. The obliterated sac has evidently formed a pad upon the inside of the abdominal wall which occludes the umbilical ring.

## Reports of Societies.

### NEW YORK SURGICAL SOCIETY.

STATED meeting, NOVEMBER 8, 1881. DR. SANDS, president, in the chair.

A MODIFICATION OF LISTER'S ANTISEPTIC DRESSING.

DR. JAMES L. LITTLE read a paper on the above subject, first directing attention to a paper which he published in the American Clinical Lectures for 1878, Vol. III., No. 11, on Lister's antiseptic method of treating surgical injuries. He there called the attention of the profession to a modification of this procedure which he had been using in the treatment of simple wounds, especially those of the hands and fingers. He had since continued its use, and had found the results in a large number of cases so satisfactory that he had deemed it of sufficient interest and importance to justify his calling attention to it again in a short paper. Although having full confidence in Mr. Lister's antiseptic method he, like many others, had long recognized a great difficulty that was encountered by the general practitioner in attempting to carry out the minute details of the dressing, and he had for a long time hoped that a more simple method, equally efficacious, might be devised. Dr. Markoe's "through drainage" was a decided step in that direction, antiseptic in character, simple, and successful in results. It was, however, appropriate only where drainage was necessary, and simple and efficient as it was it required a certain degree of attention which, while easy for a hospital surgeon, was not sufficiently so to guarantee its extended use by the general practitioner. Dr. Little then directed attention to the difficulty in procuring good antiseptic gauze to be used in Mr. Lister's dressing, and also directed attention to observations made by Dr. R. F. Weir to the effect that even when the gauze was well wrapped up in rubber cloth it

would deteriorate in a few months. He had noticed several times that the gauze used in surgical operations had no odor whatever of carbolic acid, although it had just been purchased from a responsible store.

During the last six years he had been using the following simple antiseptic dressing in small injuries, such as those inflicted by machinery, cog-wheels, and the like. Having put the parts in a condition for dressing, he washed the wound in a solution of carbolic acid, of a strength of one to twenty, then covered the parts with a thick layer of borated cotton, and then snugly and evenly applied a simple bandage, the plain, uncarbolized cheese cloth usually being used. The patient was instructed to keep the dressing wet with a solution of carbolic acid, of a strength of one to one hundred. He usually employed Squibb's solution of impure carbolic acid, of a strength of one to fifty, and diluted it with an equal bulk of water. The parts should be kept at rest, and the dressings be left undisturbed for several days unless there was pain, rise of temperature, or discharge through the dressings. Those conditions were always to be regarded as indications for redressing. In many cases where rubber drainage tubes had been used they might be removed at the second dressing, and if catgut had been used for sutures a second dressing might be allowed to remain for an indefinite period. In a number of cases of lacerated wounds he had allowed the first dressing to remain until the wound had entirely healed. He had treated nearly three hundred cases of open wounds in this manner, and not one of this number had been followed by inflammatory symptoms. Extensive lacerated wounds had healed, and dead tissue had sloughed away without giving rise to any of the so-called symptoms of inflammation. In no case had there been reddening of the skin along the course of the lymphatics or tenderness of the glands, and no counter-opening had been necessary. Anodynes had not been needed save in a single case, and then for only a single night to control slight restlessness. Recently he had used this modified dressing in St. Vincent's Hospital in a case of amputation of the leg. The method of amputation was that by lateral skin flaps and circular incision through the muscle. All the details of Lister were employed except the spray. Catgut was used for ligatures and sutures. Short drainage tubes were placed in the anterior and posterior angles of the wound. After the wound was washed with a solution of carbolic acid, strength one to twenty, it was dressed with several layers of dry borated cotton, and the gauze bandage applied. The outside dressing was kept constantly wet with a solution of one to forty of carbolic acid. Four days after the operation there had been no unfavorable symptoms, and on removing the dressing the cotton was found not to have been wet through by the carbolic acid lotion. The layer in immediate contact with the wound was saturated with a watery discharge. The wound was perfectly aseptic. Eight days after the operation the dressing was removed, and the wound was entirely healed except at a small point at the lower angle. The value of cotton-wool as an antiseptic dressing, he thought, was not fully appreciated by the profession. M. Guerin, of Paris, in 1872, and since then Mr. Gamgee, of Birmingham, England, had called attention to its great value. Used in the way he had indicated it seemed to Dr. Little to be as perfect an antiseptic dressing as gauze and other materials recommended by Mr. Lister, while at the same time it was free from all of the objections that per-

tained to the latter, and which materially prevented its use by the general practitioner. If applied in sufficient quantities around an open wound it protected it thoroughly from the "floating matter of the air," which was supposed to be the real cause of suppuration. It was the best germ filter known, as had been proven by Tyndall.

Dr. Little uses borated cotton containing fifteen per cent. of boric acid, keeping it wet externally with a solution of carbolic acid, which renders it more surely antiseptic. Full precautions to render instruments, sponges, and the hands of the surgeon antiseptic should not be neglected, and drainage tubes, if necessary, should be used. Catgut or torsion should be used to arrest hemorrhage. The spray might be resorted to if thought necessary. The borated cotton remained unchanged for months. The fact that this dressing need not be made oftener than once in several days especially recommended it to the country physician. At the second dressing he usually applied carbolized oil to the surface of the wound to facilitate removal of the cotton. He had used this method of dressing in one case of compound fracture, and although the case had not yet terminated, it seemed to be doing as well as it would under full Lister dressing.

Dr. MASON had used salicylated cotton covered with an ordinary bandage, and had been as much gratified with the results as with the regular Lister dressing. He had used ordinary cotton in two cases of amputation, one did well and the other not. He had also used salicylated cotton in two cases of removal of the breast; in one case the wound was healed in four days, and on the twelfth day the patient was about the house. Eight months afterwards the other breast was removed for the same disease—cancer—and the wound healed as rapidly as did that after the first operation. He had had the same result after the removal of a large, fatty tumor of the back, but in all of these cases he first applied a protective—a piece of oiled silk—to prevent the cotton from adhering to the surface of the wound. He did not keep the parts wet with carbolic acid, but simply washed the wound with a solution of carbolic acid, and then applied the dressing.

Dr. L. A. STIMSON thought that the results obtained by Guerin's dressing could not be used as an argument in favor of the antiseptic Lister dressing, because the two differed radically in their methods. The Lister aimed to keep the wound absolutely aseptic, while with the Guerin dressing putrefaction of the discharges was invariably present, and its value depended upon other factors. Not a few attempts had been made to simplify the Lister antiseptic dressing, and one which resembled Dr. Little's quite closely was that used by Verneuil in the treatment of compound fractures and amputation wounds, and consisted of purifying the wound in the first place, then covering it with a thin layer of material charged with an antiseptic agent, and over the whole was placed a thick layer of cotton, forming almost the permanent dressing adopted by Heuter. Dr. Stimson regarded it as probable that in the treatment of a wound the essential thing was to purify it before any dressing was applied, and afterwards the character of the dressing employed was of a somewhat secondary importance, provided only that there was free discharge for the secretions, and that the wound was left comparatively undisturbed.

Dr. A. C. POST had treated open wounds, where he was unable to use Lister dressing, by applying lint

soaked in carbolic oil and securing it with a bandage. He had found that wounds dressed in this manner could be left for many days without either suppuration or irritation ensuing.

DR. LANGE asked Dr. Little if he had observed carbolic acid poisoning in any of his cases.

DR. LITTLE replied that he had not. He had not seen any inconvenience whatever from its use. He had seen only one case of carbolic acid poisoning after the use of Lister's method, and that was in a large wound. The wound, however, healed almost entirely by first intention. It was washed out freely with a solution of carbolic acid.

DR. LANGE said that he did not refer to poisoning after washing out wounds with carbolic acid, but to that produced by keeping the skin constantly wet with carbolic acid.

DR. LITTLE remarked that in the case of amputation which he reported the dressings next the skin were not wet, but in all the other cases, as a rule, the solution penetrated all the dressings. He had tried the dry dressing and had found it painful in several cases, and the patients had gone back voluntarily to the moist dressings which had been kept on until the granulations were well established, and no unfavorable results had followed.

DR. LANGE remarked that he had seen unfavorable results following the application of disinfected jute which was constantly kept wet with carbolic acid. At the clinic in Kiel poisoning to a slight degree by carbolic acid was a very common occurrence, and there was scarcely a case of large wound dressed with carbolic dressings in which there were not some symptoms of slight poisoning. In small children he regarded such toxic effects as very dangerous.

DR. MARKOE remarked that he had had the question of carbolic acid poisoning before his mind for a long time, and especially in connection with his plan of through drainage. In that plan the internal parts are kept constantly wet with carbolic acid, usually with a weak solution, and he had not yet seen a case of poisoning produced by it. On the other hand, in cases treated in such a way that the surface of the skin is kept constantly exposed to the carbolic acid, its use had been followed by toxic effects. From these facts he had come to conclude that the chief danger in the use of carbolic acid arose from the application of the agent to the skin, and that the application of it to wounded or granulating surfaces was comparatively innocuous. He asked for the experience of the members of the Society in that direction.

DR. LANGE referred to experiments performed by Hueter, in which the application of wet dressings with carbolic acid solutions to the skin was soon followed by appearance of the acid in the urine and that the degree of absorption depended upon the quality of the skin. In children absorption took place very quickly. He thought that perpetual contact of the skin with carbolic acid was more apt to give rise to poisonous symptoms than when carbolic acid was injected into drainage tubes in through drainage; for, in the latter, the solution to a very great extent drained away and there was only a temporary contact with the wound. He had tried the borated cotton somewhat extensively and in large wounds. He had never applied it directly to the surface of the wound, as he did not any cotton dressing, because it adhered to the surface of a fresh wound, and was difficult to remove. He always first applied

layers of gauze, and then used the cotton as a kind of padding. He thought that the borated cotton was not so completely deodorizing as salicylated cotton. He had seen several wounds where a copious discharge occurred and where there was a kind of disagreeable odor that occurred after the use of borated cotton within a comparatively short time. Despite that, however, he had in a number of cases left the dressing for weeks even. He believed that the ultimate result after every wound was very much influenced by those procedures to which it had been subjected at the time of the operation or immediately after the operation, and that altogether it was rather insignificant as to what kind of antiseptic dressing was subsequently applied. Of course to a certain extent from those wounds which had a large suppurating surface absorption of decomposed secretions might occur and produce a bad effect, but in a case where there had been union by first intention to a great extent, as was in these days usually secured, it was rather an insignificant matter whether the subsequent dressings were kept entirely without decomposition or not. So far as he had been able to determine the wounds in Dr. Little's cases, many of them healed by first intention, and he thought that it could be accepted that all such wounds did very well under almost any dressing. He thought that a better test of the value of the dressing would be obtained in cases of large wounds in which union took place largely by granulation.

DR. LITTLE remarked that in most of his cases the wound healed by granulation.

DR. LANGE remarked that if the wound was actually healed in the deeper parts and only a small granulating surface left it was not so apt to become affected by the poison. In reply to a question he said that he had not seen any injurious effects follow the use of the borated cotton.

DR. POOLE said that the objection to the cotton on account of its adhering to the surface of the wound could be overcome by using picked lint. With reference to poisoning from carbolic acid following its injection into drainage tubes, he had used through drainage in excision of large joints in five cases, and had not seen any unfavorable results.

DR. STIMSON in reply to Dr. Markoe's question referred to a case in which he had removed a portion of bone from the elbow joint. The wound was offensive, and it was washed out four times a day with a solution of carbolic acid, and between the washings the dry Lister dressing was employed. On the fourth day there were distinct evidences of carbolic acid poisoning. The urine was green, the temperature was lowered, and the pupils were contracted. The temperature subsequently fell to 92.5° F., the pupils contracted to pin-holes, and the respirations were reduced to six in number. The patient, however, rallied nicely and made a good recovery.

DR. MASON had had some experience in the use of through drainage; had employed a weak solution of carbolic acid, and had not seen any poisonous effects follow its use.

DR. LANGE remarked that slight degrees of carbolic acid poisoning could be easily overlooked. There were many patients who in the first days after the operation suffered from gastric catarrh and from headache, and in whose urine carbolic acid could be detected, although it had not produced any change in the color of the urine. Sometimes the color of the urine

was changed only after it had been exposed to the air a number of hours. Headache and gastric catarrh were of very common occurrence in such cases and persisted longer than they usually did when due simply to the effect of the ether or chloroform. Besides, the power to resist the action of the poison varied in different persons.

Dr. BRIDGEMAN thought that the benefit derived from the Lister dressing depended upon the infrequency with which it was applied, thus avoiding disturbance of the parts involved in the operation or injury. He thought that symptoms of carbolic acid poisoning were more apt to be produced when a weak solution was used than when a strong one was employed. He thought that strong injections of carbolic acid would be apt to produce a cauterizing effect, and in that way prevent absorption. He had noticed that carbolized oil, one to twelve, when applied to the skin produced a good deal of irritation and destruction of the superficial epidermal layers. A much weaker solution answered all practical purposes. With reference to the absence of odor in the antiseptic gauze referred to by Dr. Little, he thought that in many fresh samples produced at the stores no odor could be detected, and yet the article was efficient. The odor of carbolic acid could not be detected in any recently prepared gauze, no more than it could be in carbolized oil. He believed that the objection urged by Dr. Lange to the use of cotton on account of its adhering to the surface of the wound did not hold good, as it was improper to attempt to remove the cotton until it was loosened by the discharges. He believed that the less wounds were dressed the better would be the progress made in them. Any means which did away with the necessity for frequent dressings contributed to antiseptic and to the healing process.

Dr. LANGE believed that the longer the cotton remained in contact with the wound the firmer it became united with the granulations and the more difficult it was to remove, and when removed small hemorrhages were liable to occur. All of that could be prevented by first applying several layers of gauze.

Dr. LITTLE remarked that he had had but little trouble in removing the cotton, the parts being kept wet, and besides the carbolic acid gave rise to a watery discharge which facilitated its removal. After the first dressing the cotton usually adhered to the surface of the wound, but before attempting its removal he always had it well soaked and then had experienced no special difficulty. After granulations had appeared it had been loosened by the slight discharge and was nowhere adherent except at the edges of the wound, and there on account of the drying of the secretion.

Dr. MARKOE said that it might be interesting to refer to some experience dating before the days of antiseptics. Barron Larrey, in the Egyptian campaign, gives his experience in connection with operations performed far away from the basis of supplies, in the desert, where he was obliged to dress the wounds of the French soldiers, and then send them to Alexandria and different places on the coast. They were removed, and necessarily without much care, and he subsequently found that many of the cases of trephining and of compound fracture, amputations, and operations of various kinds had been without dressing for many weeks, and that while some of them were exceedingly foul and filled with maggots, he was astonished to find how perfectly well they all had done. Perhaps there

was something in that experience which, to a certain extent, had been overlooked.

Dr. LITTLE remarked that before using the dressing which he had described in his paper he used dry picked lint, and the wounds did very well, but there were constant exceptions. Under the dressing recommended he had not found any cases in which the wounds did not heal without signs of inflammation.

Dr. SIMMONS thought that we could hardly speak of cotton or lint when kept moist as an air-filter.

Dr. HUTCHISON said that for several years he had dressed finger wounds with a very weak solution of carbolic acid — a drachm to a quart, that is, 1 to 250. Pieces of lint were saturated with the solution and wrapped about the finger, covered with a cot of oiled silk, and the patient was directed to remove the cot and wet the dressing three or four times a day. For larger wounds he had used instead of cotton pieces of oiled silk dipped in the above solution of carbolic acid, laying them over the wound and covering it with oakum and retaining it with a bandage. This dressing was not disturbed until it was absolutely necessary, and in the majority of cases it was not disturbed until the wound had entirely healed. He had always had the impression that carbolic acid had been used unnecessarily strong. In 1867 he saw it used by Maisonneuve in the wards of the Hotel Dieu, in Paris, and soon afterwards it was used by Mr. Lister. Subsequently he asked Dr. Squibb to ascertain how weak a solution would preserve meat, and it was found that meat was perfectly preserved in a solution of the strength of 1 to 250, that is, a drachm to a quart. Dr. Hutchison then began to use a solution of that strength and had continued to employ it ever since. He had used it extensively upon the surface of large burns involving as much as one half the entire body. His method had been to saturate lint in a solution and apply it over the burn, and the effect had been to almost instantaneously relieve the suffering of the patient, and he had not seen carbolic acid poisoning following its use. Its local effects are anæsthetic and antiphlogistic as well as antiseptic. He had not seen toxic effects produced by this weak solution except in one case, that of an abdominal abscess where there was a large cavity. After the discharge of the pus the cavity was injected with the solution, all of which was not removed. In that case carbolic acid poisoning occurred. But he supposed that it was due, however, to the fact that the solution used was so weak. A solution of a strength of one to twenty was quite caustic, and absorption would not be so likely to occur as after the use of the weaker solution. The oakum dressing in his hand had proved very satisfactory. Its good effects are due to the carbolic acid, creosote, and various empyreumatic oils contained in the tar in the oakum.

Dr. BRIDGEMAN, on bearing upon the action of the carbolic acid upon the skin, referred to a case of confluent small-pox, in which, to destroy the odor, the patient was anointed from head to foot with carbolized oil, of a strength of one drachm to eight ounces. The patient recovered, and did not exhibit any symptoms of carbolic acid poisoning.

Dr. LANGE doubted whether a disposition to absorption was very great in cases where the skin had been elevated, and the secretions laid between the epidermis and the cutis.

Dr. BRIDGEMAN thought that absorption could take place in these cases as evidenced by the rise of tem-

perature which usually occurred at about that period in the disease.

DR. SIMMONS referred to three fatal cases mentioned by Langenbeck, in which carbolic acid poisoning took place from washing the body for the cure of scabies. Only one washing was made, and the strength used was one to forty.

DR. LANGE remarked that it had been stated that assistants and nurses were poisoned by constant contact with the spray.

DR. POST asked if any instance of carbolic acid poisoning were upon record in which carbolized oil had been used. He had used Dr. Markoe's plan of through drainage quite extensively, and had not seen any cases in which toxic effects had been produced.

THE PRESIDENT said it seemed to him that two questions were suggested by the paper: one was the cause of the success which Dr. Little had obtained with the dressing advocated, and the other the value of this as a substitute for Lister's dressing in the treatment of wounds. With regard to the *modus operandi* of the dressing, he thought it had been shown that whatever of success had been obtained could hardly be ascribed to the boracic acid, inasmuch as the boracic acid was in contact with the wound for so short a time, being washed out by the carbolic acid solution. Neither could the success be ascribed to the action of the cotton as a filter, for when the cotton became wet it lost its power in this respect. He thought it might be a question whether success was not largely due to the infrequent renewal of the dressings, and to their being saturated with a solution of carbolic acid. With reference to the substitution of this mode of dressing for that used by Lister, he should hardly be willing to recommend it without further testimony, as the wounds treated were not such as would test the efficacy of the method. If such a dressing were found to insure success after major amputations or operations for the removal of large tumors, he thought its claims to superiority would be acknowledged.

DR. POST remarked that lacerated wounds of the fingers were frequently followed by suppurative.

THE PRESIDENT remarked that in his experience they usually did well under any ordinary dressing. He further remarked that the known poisonous properties of carbolic acid, and its tendency to keep up suppuration and retard the healing of wounds would stimulate surgeons to seek for some substitute for it.

Within the last few months he had been much interested in the use of iodoform as an antiseptic dressing. His attention was called to its use about six months ago in a German journal, where he read that iodoform had been proposed by Dr. Mosetig-Moorhof as an antiseptic dressing in gangrenous and unhealthy ulcers. It was claimed that the application of iodoform changed the character of the ulcers, and promoted speedy cure. He began its use in the Roosevelt Hospital, and was pleased with its action. During his recent visit to Vienna he saw the agent used in Billroth's clinic, and had since adopted it. The method of application varied in different cases. In wounds which had a surface which could not be covered, such as that left after extirpation of the tongue, iodoform was simply dusted on the wound with an ordinary dredging-box. In the treatment of amputations and of large wounds generally, as well as small ones, the mode of procedure was the following: The wound was freely irrigated with a solution of carbolic acid during the operation, a drain-

age tube was inserted, and after being closed with sutures the wound was covered with about six or eight pieces of cheese cloth upon which had been sprinkled a quantity of iodoform sufficient to cover it; over this gauze was placed a large quantity of ordinary absorbent cotton, then a piece of oiled muslin, and finally a gauze bandage. That was the method which had been employed in Billroth's clinic during the present year, and the results, it was stated, had been excellent. Dr. Sands had had good success with it in two amputations, in several compound fractures, and in a number of lacerated wounds of the hands and feet. The iodoform seemed to act as a deodorizer quite as well as carbolic acid, and he had witnessed no ill effects from its use. It had been claimed for iodoform dressing that although iodine was absorbed, and appeared in the urine, no ill effects ensued, and that the method was free from the dangers which attended the use of carbolic acid.

DR. G. A. PETERS had treated lacerated wounds of the hands and feet with good results by the use of lint saturated with laudanum, and changed but seldom.

DR. MASON said that the surgeons at Charity Hospital at one time used iodoform in the treatment of all sloughing venereal sores, and with good results.

DR. MARKOE said that he had used iodoform with great freedom, and without bad consequences.

The Society then proceeded to the transaction of miscellaneous business.

## PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

BILATERAL LACERATION OF THE UTERINE CERVIX, OF FIVE YEARS' STANDING, COMPLICATED WITH PROCDENTIA; RECOVERY.

APRIL 9, 1881. Paper on Bilateral Laceration of the Uterine Cervix, read by DR. BIXBY. Reserved for publication.

DR. STEDMAN inquired why the operation performed by Dr. Bixby was preferable to amputation and uniting the edges of the mucous membrane over the stump.

DR. BIXBY replied that the cervix was very large and the lacerations deep.

DR. BOARDMAN asked Dr. Stedman what advantage there was in amputation.

DR. STEDMAN replied to [Dr. Boardman] that there was plainly no advantage in Dr. Bixby's case, but that in a case of his own where there was plenty of room, and especially in case of elongated cervix, there was a gain in the simpler procedure.

DR. BOARDMAN said he did not believe in elongated cervix, the so-called elongation being apparent rather than real, and due to a telescopic dragging out of the parietal tissues around the cervix as the uterus becomes thrust into the cavity of the vagina.

DR. BOARDMAN also took exception to the method by amputation, believing it to be better practice to restore the parts to their normal relation, and so to avoid the risk of future miscarriage and other ills known to be incident to the condition resulting after amputation of the cervix.

DR. BOARDMAN stated that he had formerly considered silk sutures good in cases where there was little tension, but the result in a recent case had convinced

him that they cannot always be relied upon in such cases.

Dr. BIXBY stated that he had used catgut in one case and had never looked at his sutures again, — these had been left to take care of themselves. The union was perfect and the woman had subsequently given birth without accident.

#### THE NECESSITY OF USING THE LONG NOZZLE IN MAKING INTRA-UTERINE INJECTIONS AFTER CONFINEMENT.<sup>1</sup>

A paper was read by Dr. FORSTER at the preceding meeting.

Dr. Forster stated that the carbolic solution referred to as having been used in the case first detailed was of the strength of about five per cent.

The discussion on this paper was adjourned to the present meeting.

Dr. FORSTER reiterated his firm belief in the necessity of using the long nozzle, in intra-uterine injections. He had used carbolic acid, but on account of the possibility of the acid not being dissolved by the water, and thus perhaps accounting for some fatal cases, he should in future use permanganate of potash, or thymol, the objection to the expense of the latter being met by the relatively small quantity necessary for disinfection. During the past winter he had used large quantities of thymol in surgical cases of the strength of one part to 2000 water, and was much pleased with it.

Dr. MINOT related the case of a patient, primipara, who had had a perfectly normal labor. Intra-vaginal injections of a solution of carbolic acid were given daily with care, by an experienced nurse. On the fourteenth day, while an injection was being given, the patient suddenly cried out with pain, became very pale, and fell into a kind of collapse with very rapid pulse. She recovered in an hour, and did not appear to have suffered any permanent injury, though her convalescence was somewhat protracted, and the milk, which was abundant at first, almost disappeared in the course of six or eight weeks. A similar case was reported by Dr. W. T. Smith, of Hanover, N. H.<sup>2</sup> Dr. Minot stated that in his own case the injections were used blood-warm, without force, in amount not exceeding two ounces, and by the aid of an ordinary Davidson's syringe with a central aperture. The strength of the solution was about two per cent.

Dr. RICHARDSON said he would confirm the point as brought out by Dr. Forster, — the use of the long tube and the thorough washing out of the uterus. The one was not possible without the other. Short tubes had no effect. At the hospital whenever there had appeared the least suspicion of trouble the intra-uterine injections were immediately employed. There was no doubt that this procedure had saved lives. Dr. Richardson gave the temperature records of three cases, showing a remarkable improvement in almost every instance, the washing out, whether by a two to two and a half per cent solution of carbolic acid or a weak solution of permanganate of potash, having been followed by a marked reduction of temperature which was either permanent and requiring no further attention, or slowly rose again, necessitating the occasional repetition of the process.

Dr. Richardson remarked that when this antiseptic treatment first started the risk of poisoning by carbolic

acid was urged as an objection, but he had never seen the slightest unpleasant effects from hundreds of intra-uterine injections. Cases of poisoning by this agent, such as have been reported, he thought were due to a careless use, especially from a failure to shake thoroughly before using a solution of some strength, in which the acid is more or less separate and falls to the bottom, whence it is liable to be taken up by the syringe in undue quantity. It was necessary also to have the water a little hotter at the start than the temperature designed at the moment of injection on account of the necessary cooling during preparations. With these precautions Dr. Richardson repeated his belief that there was not the slightest danger to be feared from the use of intra-uterine injections. In one instance in which the inner os was closed Dr. Richardson had used a double catheter to insure ready exit of the injected fluid. It was astonishing to see the amount of putrid, shreddy, very offensive debris of decomposed matter brought away by the proper method even after the repeated use of the vaginal douche. In one such case there had not been the slightest offensive discharge preceding the washing out, a chill and high temperature alone having been the indications for the procedure.

Dr. ABBOT remarked upon the value of chlorinated soda in empyema, and its decided advantage in a given case over a one per cent. solution of carbolic acid, a one fifth of one per cent. solution of thymol, and a solution of permanganate of potash, which had been successively tried without effect upon the excessively fetid discharge. Water containing ten per cent. of the liquor sodæ chlorinate was then employed with the most complete success, and the pus diminished so rapidly that at the end of ten days not a drop could be obtained, nor was any found in the pleural cavity at the autopsy. Dr. Abbot observed that there was no question of the safety of the soda solution, and thought it would be well worth trying as a material for intra-uterine injection.

Dr. BOARDMAN said he would confirm the remarks already made, and referred to his unpleasant experience with a series of cases of septicæmia in the Lying-In Hospital, several resulting in death, while the recovery of others was greatly due to intra-uterine injections, whose immediate as well as remote effects were very marked. Dr. Boardman thought that it might in some cases be advisable to use thymol, a more agreeable substance than carbolic acid, and in cases of organic diseases of the uterus quite as effective. Its greater expense is somewhat offset by the less quantity required, while a more general use would increase the production, and diminish the cost.

Dr. LYMAN stated that intra-uterine injections had been followed up at the City Hospital with a good deal of advantage. He had used them in cases of sloughing fibroids and after abortions, of which there had been a considerable number at the hospital. Reduction of the temperature and arrest of the septic symptoms had been a very uniform result. A chill had followed in some cases, but this did not seem to have been of serious import. In one case of retained placenta with foul discharges he had not been quite sure whether the reduction of the temperature had been due to the injection or to the large dose (thirty grains) of quinine, given at the same time. Dr. Lyman was entirely of the opinion that many so-called intra-uterine injections were simply vaginal from the imperfect methods and appliances used, whereby the fluid failed to reach the

<sup>1</sup> See JOURNAL of May 12, 1881, page 436.

<sup>2</sup> See The Medical Record, January 22, 1881, page 112.

uterine cavity. He had seen no harm, on the contrary, he could look back upon one or two cases of his own, in which the autopsy revealed lymphangitis, which he believed might have been saved had the uterine been thoroughly washed out early in the disease. It was not worth while to wait for offensive discharges before beginning this treatment, as sepsis may be thoroughly established, the discharges remaining free from odor. Dr. Lyman referred to some remarkable cases which had been under the care of Dr. Chadwick many years ago in which this treatment was successfully followed. He thought that if a diagnosis, as between lymphangitis, general sepsis, and phlegmasia alba dolens, could be made in advance, cases suitable for washing out could be selected with more discrimination, and those could be indicated in which injections would be of questionable advantage. In cases of pelvic abscess he would almost invariably use the injections.

Dr. Lyman detailed the case of a prostitute brought to the hospital in a state of collapse, with foul discharges from the vagina, the results of a criminal abortion. The relief to the patient's whole appearance upon the first thorough washing out of the uterus was something marvelous. The day following there was a chill, resulting probably from either reaccumulation or a separate collection, and it was then discovered that some instrument had penetrated Douglas's pouch. The washings were continued every two hours with a three per cent. solution of permanganate of potash, and the patient's life was eventually saved after a most unpromising beginning. Dr. Lyman declared that there was nothing more important in obstetrics than a thorough knowledge of the subject of uterine injections. Dr. Lyman cited another case, seen with Dr. Chadwick, that of a woman in whom an abortion had been committed by a man with no pretense to a medical education. The patient was in a very critical condition. Dr. Draper was called in with reference to an ante-mortem statement. The woman recovered, however, and apparently from the persistent use of intra-uterine injections.

Dr. RICHARDSON stated that the same fall of temperature had taken place in cases in which no quinine whatever had been given; whether quinine had been given in the three cases charted he could not say.

Dr. DRAPER asked whether in hospital or in private obstetric practice any observations had been made concerning the effects of simple warm-water injections, or, to put the question in another form, what evidence there was that medicated or disinfectant injections were superior to non-medicated lotions, since the chief object of the local treatment has been stated to be the removal of the decomposing contents of the uterine cavity?

Dr. RICHARDSON replied to this question that injection of warm water had been tried at the Lying-In Hospital in some half dozen cases with the result that although the temperature fell in each case much as in the others, yet it very soon rose again, which it did not in the cases in which the carbolic acid had been used, as if this had had a beneficial action upon matters not at the time washed out.

Dr. SINCLAIR said that intra-uterine injections had been used the last fifteen months at the Boston Lying-In Hospital, and that there was little or no danger except in case of dilated uterus with constricted neck. If it were found that the fluid did not return it was

pretty good evidence of this condition, and uterine colic was likely to ensue.

Dr. C. E. STEDMAN said he could confirm in the highest degree the value of intra-uterine injections. He had used for this purpose a common male catheter with the curve modified. Soon after this subject began to be discussed he reported to this Society a case under his observation where quinine in large doses was used with hot carbolized intra-uterine injections, with the happiest results, although the patient was in the most hope-less condition for days.

Dr. Stedman inquired of Dr. Richardson the mortality from septicæmia at the Lying-In Hospital as affected by the procedure in comparison with results of the old methods of treating these cases.

Dr. RICHARDSON stated that in the last epidemic of puerperal septicæmia at the hospital eight out of eleven cases recovered under this treatment.

Dr. SINCLAIR said he remembered two cases of typhoid fever occurring at the South End in a house whose soil pipe failed by the space of six inches to reach the drain, leaving a perfectly free opening by which the gases entered the house. A case of typhoid fever which occurred in the next house was supposed to be referable to the same cause.

#### THE MENOPAD. — THE SPECULUM.

Dr. BROWN exhibited and described a device invented and patented by a physician to take the place of the monthly napkins, and known as a menopad. In this apparatus the discharge is received and retained by a roll of absorbent cotton, which can be changed from time to time.

Dr. BIXBY said in answer to a question that he had used both Sims's and Cusco's specula, and that he considered the former for operations when held by an assistant the best speculum ever invented, while he preferred the Cusco for all ordinary work, and used it daily and almost exclusively except in the case of very young women. It was important that the instrument should be well lubricated in order to be introduced to the fullest extent. When properly done there is no possibility of unduly dilating the orifice of the vagina when the blades are expanded. In the dorsal position the Cusco is used with the handles upward.

Dr. BOARDMAN remarked that all must agree that no instrument can compete with the Sims speculum, but this requires the aid of an intelligent assistant, which it is the exception to have. After an extended trial of all forms he had come now to employ almost exclusively the Higbee bivalve, the principal advantages of which are to be found in its short upper blade and minimum expansion at the vulva. With Cusco's speculum there is more expansion at the vulva than with any size of the other, and its upper blade, equal in length to the lower, is very likely to get behind, and lift the cervix so as to prevent the proper view without special adjustment. With Higbee's this never occurs. Dr. Boardman had long discarded all forms of the cylindrical speculum.

Dr. RICHARDSON said he agreed with Dr. Boardman, and in the women's room at the Massachusetts General Hospital had used Higbee's speculum exclusively.

Dr. BIXBY further said that he had used Cusco's speculum for fifteen years, sometimes with the patient on her side, or, if the organ were anteverted, by preference with the patient on her back.

Dr. FORSTER exhibited and described a new form

of Davidson's syringe, called The Victor, by which the amount of injection can be accurately measured, and the possibility of injecting air obviated. The force is obtained by compressing the air in the top of the reservoir bottle by means of an air bulb.

Dr. BOARDMAN directed attention to certain objections to Nengebauer's speculum, as he had done many times before. On tilting the instrument to improve the view there was danger of injury from the pointed and sharply curved extremities, either in the way of painful pressure or actual lesion of the vaginal wall. Moreover, the constant use of the blades gives them in time a sharp cutting edge, from which he had actually seen in the vaginal mucous membrane a sharp, clean cut, two inches in length. Aside from these forms of injury nipping by the two blades was likely to occur.

### Recent Literature.

*Transactions of the American Gynecological Society.*  
Volume V., 1880. Boston: Houghton, Millin & Co.

It is greatly to be regretted that there is such a delay in the appearance of a book of so much value to the gynecologist, as these volumes from year to year become. We had hoped that after two or three years, as the work of the Society became more systematized, this great disadvantage would be overcome, but the present number is later than ever.

The papers read at the fifth annual meeting of this Society open with the Annual Address of the President, Dr. J. Marion Sims, the subject of which is various changes in the constitution which he suggests; a rather unpleasant, and generally thankless, task, yet it is done most conscientiously. Of whatever value this may be to the Society, the general reader will undoubtedly be disappointed that the time was not devoted to the consideration of some one of the many subjects in gynecology which the honored President was most fitted to discuss, and which always come with so much force and interest from him.

Dr. Batten contributes a short paper on The Proper Field for Battey's Operation, and very wisely inclines to conservatism. In the enthusiasm with which abdominal surgery is cultivated it is certainly in danger of being too often performed, and the writer very properly lays considerable emphasis on the moral considerations, which should never be lost sight of.

The paper by Dr. A. Reeves Jackson on Uterine Massage as a Means of Treating Certain Forms of Enlargement of the Womb is valuable as helping to define the proper field of this comparatively new method of treatment. It might have been enlarged, according to our experience, to include those cases of lateral flexion and version due to old pelvic cellulitis, where there is thickening of the broad ligament on one side or the other. In such cases, where pessaries can accomplish so little, massage, especially directed to the thickened part, will favor absorption and materially increase the mobility of the organ.

The paper by Dr. H. P. C. Wilson on Ovariectomy during Pregnancy called forth considerable discussion, and the conclusions to be drawn both from the paper itself and the subsequent debate seem to be pretty clearly these: If the tumor is small, and not likely to prevent the woman going safely to full term, non-

interference; if large, operate for the sake both of mother and child, ovariectomy being much safer than producing abortion. Statistics emphasize these conclusions.

Dr. George J. Engelmann contributes a most interesting and exhaustive paper on Posture in Labor, endeavoring, by observation of the methods of delivery among savage and half-civilized people, to determine what position instinct would lead a woman to assume, and, if possible, to adduce some useful hints for obstetric practice. The painstaking research, the exhaustive use of old material and the diligent acquisition of new, the graphic wood-cuts which illustrate the paper, and the careful arrangement of the various facts are beyond praise. Naturally a large part of what is new is with regard to the North American Indians, and a very complete account of their customs is the result. It is doubtful whether, if the customs of the savage tribes of other countries could be as carefully investigated, the logical deductions would be materially different. These deductions are in the main the following: That in the earlier stages of labor the woman must be guided in her actions, and in the positions assumed, by her own comfort and by the dictates of her instinct; that the dorsal decubitus (flat on the back) at the termination of labor is a most undesirable position; that an *inclined* position, kneeling, squatting, or semi-recumbent in bed, on the chair, or lap, is the one which a woman would instinctively assume; and that of these the semi-recumbent is the most serviceable. The discussion, while suggesting some minor points to be considered, in the main confirmed these views.

The paper by Dr. James R. Chadwick on The Hot Rectal Douche is a valuable contribution to our methods of treatment in certain forms of diarrhoea and in pelvic inflammations. For the first-named class of cases it has, of course, no rival in the vaginal douche. As regards the cases of pelvic inflammation, while as a rule the hot vaginal injection is readily given, and acts most satisfactorily, yet there are cases where the rectal symptoms, or those referred to the back, are prominent, in which the rectal douche would undoubtedly do better.

Dr. W. L. Richardson's paper on Manual Dilatation of the Os Uteri as a Means of Inducing Premature Labor brings again before the profession a method which seems to have certain decided advantages over any other, but which has been strangely overlooked by writers in general.

Other papers were contributed by Dr. W. H. Byford, on The Successful Extirpation of an Encephaloid Kidney; by Dr. Theophilus Parvin, on Secondary Puerperal Metrorrhagia; by Dr. W. T. Howard, of Three Fatal Cases of Rupture of the Uterus, with Laparotomy; by Dr. J. A. Eve, on Occlusion of the Gravid Uterus; by Dr. H. F. Campbell, on The Prophylactic and Therapeutic Value of Quinine in Gynecic and Obstetric Practice; and by Dr. C. D. Palmer, on Laparotomy and Laparo-Hysterotomy, their Indications and Statistics, for Fibroid Tumors of the Uterus.

This volume of Transactions, if not perhaps as remarkable for the breadth and importance of the articles as some which have preceded it, is yet a worthy successor of those of former years, and like them forms a most valuable contribution to our gynecological literature. Its letterpress and binding show the same good taste.

# Medical and Surgical Journal.

THURSDAY, JANUARY 5, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

## INTRODUCTORY TO 1882.

THE beginning of a new year again brings round to us the occasion to thank our readers and contributors for their support and encouragement in the past, to express our hopes of a steady increase in the numbers of both in the future, to offer them the greetings of the season and many good wishes.

In so far as the JOURNAL has been true to the standard which it set for itself, and to the promises made to its readers when its form was changed, and again at the beginning of the past year, in just so far those charged with its management feel that they have established a legitimate claim upon the consideration of a constituency which should embrace all who are interested in the progress and dissemination of sound medical learning and information, in the advocacy and vindication of the highest professional and social interests. Such consideration, though naturally manifesting itself most promptly and strongly in the part of the country where the JOURNAL is published, from the cosmopolitan character impressed upon the publication at the out-set, need not be, as in fact it is not, restricted by local limits. As is well known, though perhaps not as widely as it should be, the JOURNAL is the organ or property of no individual, or clique, or publishing house. Its almost unique position in this respect, at least in this country, gives it peculiar advantages for candid and impartial discussion and publication.

In addressing its readers last year allusion was made to the marked revival of activity and interest in medical society work, at least locally, being simultaneous with increased facilities for promptly making public the papers and proceedings of the meetings. Such activity and interest doubtless have their natural periods of ebb and flow, but we do not doubt that we then picked out one chief factor in the production of a season of high tides, and that the interest of the participants is in a pretty direct ratio to the size of the audience. Whenever the principal medical societies in various parts of the country are ripe for a more general report of their proceedings the JOURNAL will be found ready to coöperate in bringing about a result which it can scarcely be questioned must sooner or later be reached in the United States, as elsewhere.

In the mean time, to such medical societies as have always found their natural outlet in the columns of the JOURNAL, which has given them in the past, and stands ready to offer them in the future, every reason-

able facility, we heartily wish a renewal and increase of vigor from year to year. It is, however, quite possible that medical societies, in Boston, at least, have not yet assumed their best, most practical, and final form, and periods do occur in their history which lead to the belief that this is even probable.

With the advent of the new year we find ourselves called upon to welcome the appearance of a new medical weekly so like in form and feature to ourselves that were it not for its tender age we should involuntarily have said, — a twin brother. We take it as a compliment to our sagacious prevision of the tastes and needs of the professional public that our new confrère, of Philadelphia, the *Medical News*, should start forth to pursue the same cosmopolitan objects, and to foster the same departments of a medical newspaper which it has been the aim of the JOURNAL to establish and develop. We are more than ever convinced that we were on the right road, a road which is broad enough for all honest travelers.

## A CONVICTION FOR CRIMINAL ABORTION.

THE recent trial in the Superior Court of Suffolk County, Massachusetts, for criminal abortion, in which a verdict of guilty was rendered, is of special interest to physicians from several points of view. The defendant, an individual of fifty or more, styling himself a homeopathic physician and prefixing "doctor" to his name, though not claiming the privilege of affixing M. D., was tried on the charge of attempting to procure an abortion upon a young, unmarried colored woman, by forcibly separating the membranes from the inner surface of the uterus over a considerable area by means of some blunt instrument, thereby opening the uterine sinuses and permitting the introduction of air into the circulation, death ensuing from air embolism. A complete account of this case, viewed in the medical and medico-legal aspects, will be given in our next issue.

In no case that has come to our notice have the advantages of the system of medical examiners over that of coroners been more forcibly shown than in this. As is well known, under the old coroner *régime*, convictions for criminal abortion were almost unknown; nor is this strange, when one considers the ample loop-holes afforded by that dangerous, but now happily obsolete, system for the escape of this as well as of other classes of offenders. Under the medical examiners, who have now been in existence four years, there have been four cases of criminal abortion brought to trial in this city, followed in three by conviction. Failure to convict in the fourth cannot be accounted for by lack of evidence of guilt, for this was by no means wholly circumstantial, but apparently its only explanation is to be found in the uncertainty of jury trials and in the influence of testimony which claimed to be and was accepted as expert, but which was not expert at all.

In the case at issue, the evidence on which the verdict was rendered was not only wholly circum-

stantial, but rested entirely on that derived from the autopsy, the data of which were so carefully and admirably worked up by Medical Examiner Draper, and the sequence of probable events rendered so certain to the jury by his clear testimony, that to this must be ascribed the verdict.

That a conviction like this will be of great value to the community cannot for a moment be doubted. For as long as such offenders against public morals and society go unpunished, they will not only pursue and enlarge their nefarious business, but it will give ample encouragement to still others to try a hand in a game where the risk is small and the pecuniary gain large. When such individuals are made to feel that five, ten, or twenty years' imprisonment is the certain result of attempting to procure a criminal abortion, then, and not till then, will the business which has reached such proportions in Boston begin to diminish. Perhaps then American women from necessity, if not from choice, may agree with their European sisters that it is better to carry children to term, and allow Nature her sway instead of rudely interfering with her, as is so common at present. To credit this conviction to the medical examiner system is to put the praise where it belongs, for we speak advisedly in saying that a like result would have been impossible under a coroner.

The sentence will not be declared until certain exceptions shall have been argued before the court, but there is every reason to hope that justice will be rendered.

A criticism that may be made of similar trials, but which was strikingly applicable in this one, is in reference to the unbridled license, if the term may be allowed, with which counsel question the experts, and compel them to disclose to an audience composed of any and all who choose to come the exact methods by which abortions can be procured, the best instruments to use, and the time in pregnancy at which the operation can be done with the greatest safety to the mother. What is to prevent any unprincipled man or woman from gaining from such a source the necessary information for beginning and successfully carrying out the trade of an abortionist? Certainly students in a medical school rarely get better instruction in this branch than can be obtained at a trial like this.

Considering, too, how rarely fatal an abortion is when produced by a trained physician, it becomes all the more dangerous to put such instruction into the hands of individuals whose prime object in using it is not the saving of life, but the filling of their pockets.

In conclusion, it is suggested to the States which are still struggling with the insufficient coroner system, in regard to which complaints have been numerous in the medical journals of late, that they follow the example of Massachusetts in establishing medical examiners, and by this means have the cases requiring it investigated by men who at the same time are learned physicians and persons of the strictest integrity.

—The first ambulance to be used in London has recently been built for the London Hospital.

## MEDICAL NOTES.

—Two additional cases of small-pox have been reported to the Board of Health during the past week. One case is that of Samuel W. Piercy, the leading support of Edwin Booth during his late engagement at the Park Theatre.

—The Stratford District (N. H.) Medical Society held its Seventy-Fourth Annual Meeting at the American House, Dover, December 21st. A large number of members were present. Dr. Ham, president of the Society, delivered the annual address, subject, A Review of the Medical Facts of the Old Testament Scriptures. Dr. T. A. Rogers, Kennebunkport, Me., delivered an oration on The Duties of a Physician. Dr. E. S. Berry, of Dover, delivered an oration on Rational *versus* Pretentious Medicine. The following officers were elected for the ensuing year: president, S. C. Whittier, Portsmouth; secretary, C. A. Fairbanks, Dover; treasurer, C. A. Tufts, Dover; council, J. R. Ham, of Dover, E. Q. Adams, of Kittery Point, and J. W. Parsons, of Portsmouth; orators, Drs. J. O. Robbins, Salmon Falls, and J. G. Hayes, Dover.

—The Danish Society for the Protection of Animals has offered two prizes for the best essays on Vivisection. The question to be treated is specially as to the replacing for medical experiments of living animals by those freshly killed.

—At a meeting of the Harveian Society, of London, on November 17th, the following resolution was passed unanimously: "That the Harveian Society of London tender a very hearty vote of congratulation to Dr. Ferrier on the happy result of the fanatical prosecution to which he has been subjected."

—Professor Pirogoff, whose death was lately announced, had for many years withdrawn from the active pursuit of his profession, and had lived on his estate in the country, where he gave his valuable advice gratuitously to the numerous patients who flocked to him from the surrounding districts. In America his name is chiefly known in connection with an amputation at the ankle-joint, in which the tuberosity of the os calcis is left in the heel flap. He was the author of a Medical History of the Crimean War, and of treatises on Orthopædic Surgery, the Surgery of Arteries, and an Atlas of Topographical Anatomy. He was the principal medical officer of the General Hospital in Sebastopol, during the Crimean War and took an active part in the introduction of plaster-of-Paris bandages.

—M. Bédard, Professor of Physiology, has succeeded M. Vulpian as Dean of the Paris Faculty of Medicine. The latter resigned the position when M. Paul Best was appointed Minister of Public Instruction.

—The Prince of Wales has lately sent presents of game for the use of the patients in several of the hospitals of London and the provinces.

—The medical world of Paris is somewhat startled by the report that the Minister of the Interior will shortly publish a decree, according to lady medical students the right to compete for the house-surgeonships hitherto denied to them.

## Miscellany.

### DR. EDWARD REYNOLDS.

It is seldom that a more useful though uneventful life has closed than that of Dr. Edward Reynolds, who died on Christmas Day. Outliving most of his contemporaries, and secluded from general society for several years by the infirmity of deafness, he will yet be remembered with respect and affection by many of the present generation who are indebted to his skill for the preservation of life and health, or for the restoration of the blessing of sight, while those whose privilege it was to know him in the intimacy of domestic life feel the loss of one whose serenity, cheerfulness, and delightful conversation have seldom been equaled.

Dr. Reynolds began the study of his profession at a period when the opportunities of obtaining a good medical education were very limited in this country, but he enjoyed the unusual advantage of spending several years in Europe, where he followed the teaching of some of the most eminent surgeons and lecturers of London and Paris, such as Abernethy, Sir Astley Cooper, Lawrence, Travers, Farre, Dupuytren, and Bichat. It was perhaps owing to the influence of these men that he acquired a preference for surgery, in which he especially excelled, although he always enjoyed an extensive general practice. He was one of the pioneers of ophthalmic surgery in this city, and his first operation for cataract was performed upon his own father, both of whose eyes he had the happiness of restoring to sight. For many years he was the leading surgeon in diseases of the eye in Boston and throughout New England. It was our privilege, while a student of medicine, to witness many of his operations for cataract, iridectomy, strabismus, etc., and we can testify both to his skill as a surgeon and to the large number of successful results which he accomplished.

To Dr. Reynolds, in conjunction with the late Dr. John Jeffries, our State as well as city owes one of its most useful and beneficent institutions, the Massachusetts Charitable Eye and Ear Infirmary. In 1824 these gentlemen opened a private dispensary, for the gratuitous treatment of the poor afflicted with diseases of the eye, in Scollay's Building, which then stood in the centre of what is now known as Scollay Square. During a period of sixteen months no less than eight hundred and eighty-six patients had applied for advice and treatment, although the population of Boston at that time did not exceed fifty thousand. The usefulness and importance of this charity being thus demonstrated, they made a successful appeal to the benevolent for the contribution of funds for the establishment of a permanent institution, which was organized under the title of the Boston Eye Infirmary, and afterwards incorporated by the legislature under its present title. After various changes of location, incident to the increasing demand for accommodation, the present Infirmary building was completed, and occupied in July, 1850, Dr. Reynolds delivering the address at its dedication. Let us hope that the State will continue to foster an institution which saves it annually from some hundreds, if not more, of paupers, for in few things is prevention better than cure than in blindness, especially among the poor, where neglect entails not only hardship to the individual but expense to the government.

During Dr. John C. Warren's absence in Europe

Dr. Reynolds was appointed to deliver the lectures on anatomy and surgery to the students of the Harvard Medical School. He was also the teacher of surgery in the Tremont Medical School.

Dr. Reynolds will be remembered with kindness by many of the profession for his sympathy with young physicians, and his ready aid and advice to them. He was unusually free from professional jealousy, and was on cordial terms with almost all his professional brethren in days when controversies between medical men were more common than is happily the case at the present time. He was a man of deep religious convictions, and was esteemed and respected by the community during the whole of his long life. He was spared many of the infirmities of old age, and his mental faculties were preserved intact. He died peacefully at the age of eighty-eight, possessing to the full "that which should accompany old age, as honor, love, obedience, troops of friends."

### RESOLUTIONS OF RESPECT TO THE MEMORY OF DR. EDWARD REYNOLDS.

At a meeting of the Surgeons of the Massachusetts Charitable Eye and Ear Infirmary, held Tuesday, December 27, 1881, the following resolutions were passed:—

*Resolved*, That we learn with unfeigned sorrow of the death of Dr. Edward Reynolds, the venerated founder of this Institution.

*Resolved*, That his early conception of the needs of such a charity and his long-continued and successful efforts to establish it, entitle him to the warmest praise and gratitude from all friends of humanity.

*Resolved*, That we recall with sincere admiration that he labored for upwards of thirty years in gratuitous ministrations to the poor, and in seeking to advance the knowledge of the treatment of diseases of the eye and ear, and that his interest in this Institution remained unabated up to the time of his death.

*Resolved*, That we feel that the example of such a long, useful, and honorable career must be of inestimable value to the community in which he lived and to the profession of which he was a distinguished member.

*Resolved*, That a copy of these resolutions be transmitted to his family with our profound sympathy for them in their great affliction.

### LETTER FROM PHILADELPHIA.

MR. EDITOR,—The meetings of the Philadelphia County Medical Society recently have exhibited an increasing interest on the part of its members, and commendable activity of the committees who provide material for discussion. In addition to the regular bi-weekly conversational meetings for the consideration of papers on special subjects presented under the auspices of the board of directors, a third meeting is held each month by direction of the committee on clinical pathology, at which cases, specimens, and clinical reports are presented, ten minutes being allowed for each, thus permitting a great variety of topics to be brought before

the Society. For instance, at the special meeting of December 21st Dr. Wm. S. Little exhibited a case of persistent hyaline artery in an adult; Dr. J. R. Evans one of supposed elephantiasis of the leg; Prof. H. C. Wood reported a case of peculiar respiratory neurosis; and Dr. C. H. Thomas one of patulous Fallopian tubes (a multipara, suffering with hamorrhage after abortion, was etherized in order to scrape mucous surface, using a wire-loop, long-handled curette, which absolutely passed into the peritoneal cavity through the Fallopian-tube of each side; no bad symptoms; pregnancy subsequently, with delivery at full term); Dr. J. Solis Cohen showed a specimen, drawings and sections, from a case of so-called primary tuberculosis of the larynx, and Dr. C. Seiler exhibited the microscopic sections of the same case; Dr. H. E. Dwight reported an instance of pregnancy complicated with cancer of the cervix, breech presentation, with successful delivery, and presented the uterus obtained at the autopsy eight months later; Dr. John Hearn made some remarks upon a rapid method of checking or reducing gonorrhoeal discharge by an old remedy formerly used by Prof. Jos. Pancoast (powdered cubeb and alum); and Dr. W. B. Atkinson exhibited a model of a gynecological chair made in New York. Such an abundant bill of fare has proved quite an attraction for these special meetings, while the new committee find themselves embarrassed with the quantity of material offered. The last two regular conversational meetings have been devoted, according to announcement, to the discussion upon Syphilis; the Clinical History of Chancere and Chancroid; the Relation of Syphilis to Scrofula; the Prevention of Syphilis by Legislative Enactment; and, finally, the Treatment of Syphilis in its Different Stages. The last-named paper was presented by Dr. E. S. Keyes, of New York, in response to an invitation from the directors. After the reading and discussion of the essay, a social meeting of the Society was held to enable the members to meet Dr. Keyes. The Library and Mutter Museum of the College of Physicians were thrown open in honor of the occasion, and some of the Fellows of the College were present. Although the evening was a stormy one a very large number was in attendance, and the informal reception passed off very agreeably.

As may be inferred the County Medical Society is in a flourishing condition, its membership amounting nearly to three hundred and fifty. It has now issued three annual volumes of Proceedings, which are more than creditable. To one not "to the manor born" the demands upon the leisure hours by the number of medical and scientific societies in Philadelphia would almost exceed belief; of course no one attends all the meetings, but most medical men, especially the younger ones, belong to several. Here is a list of the prominent ones: College of Physicians meets on the first Wednesday of each month; Philadelphia County Medical Society, second and fourth Wednesday, special meeting on third Wednesday; Philadelphia Academy of Surgery, first Monday; Pathological, second and fourth Thursdays; Obstetrical, first Thursday; Medico-Legal, third Tuesday; also the Northern Medical, second and fourth Fridays; and a number of smaller organizations in the different parts of the city. To these may be added the Academy of Natural Sciences (every Tuesday), whose biological and microscopical section many physicians attend (which holds its meetings on the first Monday of each month); the Histor-

ical Society, the American Philosophical Society, and the Franklin Institute might be added without completing the list. It is evident that the Philadelphian is a "medical society man" as well as an "*Index Medicus* man."

Medical education also seems flourishing, but, liberally supplied with hospitals as we are, the large amount of clinical material is not as fully utilized for medical instruction as is desirable for special instruction and practice. In this connection, as a sign of progress, it is noticed that the Presbyterian Hospital has recently established a dispensary service for the diseases of the ear, which is in charge of Dr. Chas. H. Burnett, who announces that he will improve the opportunity presented by giving a special course on otology. A few months ago a similar service was instituted at the Episcopal Hospital under Dr. H. A. Wilson. An illustrated course is also regularly given during the winter at the Wills' Hospital upon diseases of the eye and correction of optical defects. The public clinics on surgery and medicine are continued twice a week, as usual, at the Pennsylvania and Philadelphia Hospitals, which are of course quite independent of the clinical instruction at the ho-pitals and dispensaries of the two large colleges.

The question of mixed classes at clinics has been again precipitated at the Pennsylvania Hospital by the appearance of some females, presumably medical students, at the regular clinics early in the session, it is said by invitation of some one connected with the hospital in an official capacity. It appears that the separate, Tuesday clinics, given especially to the female students by the courtesy of the medical staff for more than ten years, have now failed to satisfy some of the more advanced advocates of women's (usurpation of men's) rights. It is assigned as a reason that the women are jealous because they entertain the opinion that the men are advanced farther in the Eleusinian mysteries than themselves, and, not satisfied to follow the Æsculapian example of having a day to themselves, they insist upon sharing the rites with the others. The medical staff unfortunately are not as united in their views of the subject as they were when the famous struggle occurred a decade ago, and the day may be lost by the assumed indifference of some influential members. Should the innovation be carried out successfully it may lead to resignations from the staff of some of its most esteemed members who are conscientiously opposed to lecturing upon medical topics to mixed classes of men and women. The whole question will probably be hotly discussed at the next annual meeting of the contributors.

The University of Pennsylvania established this winter a course for post-graduate instruction, which thus far promises well. Two courses are to be given annually, the first commenced October 31, 1881, and the second will commence early in March, 1882. A certificate is given to each person taking the course, which includes bedside and dispensary instruction in the following branches: Physical Diagnosis and Clinical Medicine by Prof. William Pepper and Dr. E. T. Bruen; Nervous Diseases and Electro Therapeutics, Prof. H. C. Wood; Dermatology, Prof. L. A. Duhring; Otology, Prof. George Strawbridge; Ophthalmology, Dr. S. D. Risley; Gynecology, Dr. B. F. Baer; and Laryngoscopy, Dr. Carl Seiler.

The number of students in attendance upon lectures at the two schools is about the same, or a little larger

than last year. The Medico-Chirurgical College is said to have nearly thirty matriculates. The Women's Medical College is thriving and has a good-sized class. Dr. William H. Parish was recently appointed Professor of Anatomy at this institution. It may be noticed as passing strange that while the ladies at the Women's Medical College are eager to have mixed clinics at the Pennsylvania Hospital, yet they are not in favor of inviting the sterner sex to their own clinics.

The fact that the County Medical Society had declared women practitioners eligible for membership was announced in a former letter; at the quarterly meeting in January several female candidates will be balloted for, and an interesting and largely attended meeting is anticipated.

PHILADELPHIA, December, 1881.

#### REFLEX CONTRACTION OF THE CORPORA CAVERNOSA.

At the meeting of the Tri-State Medical Society, recently held in St. Louis, Dr. Jno. T. Hodgen of that city presented a series of nine cases of Reflex Contraction of the Corpora Cavernosa. The main features in these cases are as follows: The presence at some portion of the cavernous body of a circumscribed area of depressed induration with distinctly marked boundaries; not painful on direct pressure, but sensitive when compressed laterally. Pain was generally present from the commencement, and both it and the hardness of the indurated patch were increased by cold and relieved by warmth. Erection was painful and accompanied by a feeling of tension in the affected portions, which became more depressed and harder, while the organ itself was bent upward or toward the right or left according to the site and extent of the induration. These cases are peculiar in that the induration was limited to certain portions of the corpora cavernosa. A generally contracted and painful condition of the penis is not uncommon, depending upon some irritation in the neighboring parts, such as results from fissure of the anus, hemorrhoids, and other painful affections of the lower bowel. The cases of Circumscribed Inflammation of the Penis reported by Professor Van Buren resemble in many points the cases here spoken of, but in his record no mention is made of the influence of cold in increasing the trouble, and the inference is that the spots were painful only upon erection. In presenting Dr. Hodgen's explanation of these cases we shall quote his own words as reported in the *St. Louis Courier of Medicine* for November, premising that syphilis was carefully excluded in them all. He says: "In seeking an explanation of the anomalous symptoms, I would call attention to the structure of the cavernous bodies. These are composed of a strong fibrous envelope, with cords running in every direction, from wall to wall, and joining one with another at every imaginable angle, leaving spaces lined with squamous epithelium. Communicating with these spaces are the arteries and veins, through which the blood is admitted to the spaces and returned from them. Besides these spaces the vessels themselves are exceedingly tortuous and capable of much distention. These vessels permit an enlargement of the organ limited only by the resistance of the fibrous envelope, which is also sustained in its resistance by the fibrous cords that pass from point to point. The fibrous envelope as also the trabeculae, are composed

of white fibres, yellow, elastic, and plain muscular tissue. Now the great hardness which may be presented by the penis during erection, is not observed when the organ has reached its extreme dimensions, and this extreme firmness cannot be due to the presence of the blood driven by the heart's action, but is due to the blood being prevented from returning to the general circulation by the erector penis, accelerator urinae, and compressor urethrae muscles, and these muscles compress the arteries as well as the veins terminating in the body of the organ. Now when the part has reached its condition of extreme distention the organic muscular tissue entering into the structure of the fibrous envelope and trabeculae of the organ contracting gives the penis the hardness and stiffness which fits it for penetration in the performance of its special function. So that while distention with blood is important in increasing the size of the organ, the peculiar hardness of extreme erection is due to contraction of the cavernous structures. Perhaps it is the personal experience of every one that when much chilled, and especially when suddenly chilled, as when taking a cold bath, the penis becomes very firm and small and much retracted, while it retains little blood. The condition here presented is due to the tonic spasm of the plain muscular tissue of the organ, as the skin under like circumstances becomes shriveled from the contraction of its muscular element, and the serotum particularly presents marked corrugations from the same cause. It has occurred to me to suggest that the contracted, indurated patches found in the penis in the cases reported are due to a tonic contraction of a limited part of the plain muscular tissue, and the depressed contractions presented during erection are the result of the closure of the trabecular inter-spaces so that little blood could enter them during erection. The influence of cold in increasing temporarily the pain and hardness indicates the probable truth of the above explanation." This contraction of the muscular element of the corpora cavernosa is supposed to be of reflex origin, and in all of the cases reported the peripheral source of irritation was found, except in one, which is still under observation. In three cases it was cold applied to the general cutaneous surface, the patients having been exposed to cold, damp weather. Why this should result in a localized contraction of the cavernous body is not satisfactorily explained, but the author suggests that it is due to an unusual excitability of the centres with which the nerve fibres of that particular spot are connected, which excitability may be owing to an unnatural stimulation of passion, which being long continued may have resulted in a hyper-irritability of certain parts of those centres whose united and properly coordinated action would have resulted in complete erection. Some show of probability is given to this explanation from the fact that these patients were all past middle life, where it is fair to presume that the ardor of youth was failing and a resort to abnormal stimulation would be very natural. In one case the cause of the trouble was found in irritable preputial ulcers. These being cured the induration gradually disappeared. In another the source was pruritus ani; in two the irritation was prostatic and in one urethral. The origin of the irritation in the remaining case has not yet been determined. The treatment pursued was to detect the source of the peripheral irritation and remove it. Where this could be done the result was very satisfactory.

## DISCHARGE OF CEREBRO-SPINAL FLUID FROM THE NARES.

THE case lately quoted from the *Lancet* was the occasion of the following communication on the same subject:—

Some time since a gentleman, in crossing from Cork to Bristol, fell down the cabin stairs of a steamer, alighting on his head. I saw him some fourteen days subsequently on his return to this city. He was then nearly quite blind; there existed the remains of severe ecchymosis of both orbits, and, on examination with the ophthalmoscope, I found hemorrhagic eruption on both retinae, more particularly the right; the pupils were unequally dilated, but responded equally to atropine; he had a discharge of clear straw-colored fluid from the nose, evidently cerebro-spinal; at times this was profuse; he was both amnesic and aphasic, and his mental faculties were seriously impaired. For example, though apparently recognizing me, whom he had known for years, he called me Dr. —, naming a connection of mine in the profession, and this he con-

tinued to do until he had partially recovered. He did everything in a half mechanical manner; his taste was affected. After a few weeks the vision of one eye improved greatly, so much so that he could walk out, shave himself, and see ordinary objects. He lost a great deal of the confusion he had regarding names, and his memory recovered itself to a certain extent. There were remissions of these attacks. He would then relapse into a stupid, drowsy condition, the fluid coming more profusely from the nares; his appetite was not much affected. Suddenly, about eight weeks after the injury, a great discharge of the nasal fluid took place, he became drowsy and comatose, and having remained in that state for a few days, he died. He was attended, with me, by Professor O'Connor, of Cork. The discharge of the fluid from the nares in this case is one of the peculiar features of it, as the instances are very few where such has been observed."

I am, sir, yours faithfully,

H. MACNAUGHTON JONES.

CORK, December 6, 1881.

## REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 21, 1881.

Deaths reported 2399 (no reports from St. Louis and New Orleans, Buffalo, or New Haven): 913 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 603, consumption 337, lung diseases 333, typhoid fever 63, diphtheria 218, scarlet fever 1.6, small-pox 90, typhoid fever 21, diarrhoeal diseases 33, whooping-cough 22, malarial fevers 21, measles 15, erysipelas 12, cerebro-spinal meningitis 10, puerperal

fever three. From *scarlet fever*, New York 82, Brooklyn 17, Philadelphia six, Chicago and Pittsburgh three each, Boston, Milwaukee, Providence, Lynn, and Springfield one each. From *small-pox*, Chicago 27, Pittsburgh 25, Cincinnati 14, New York and Philadelphia 11 each, Brooklyn and Holyoke one each. From *whooping-cough*, New York 10, Brooklyn three, Chicago, Boston, and Baltimore two each, Philadelphia, Cincinnati, and Providence one each. From *malarial fevers*, New York 13

Brooklyn eight. From *measles*, New York 11, Brooklyn two, Chicago and Pittsburg one each. From *erysipelas*, New York four, Boston three, Philadelphia two, Chicago, Baltimore, and Somerville one each. From *cerebro-spinal meningitis*, New York six, Baltimore, Worcester, Springfield, and Somerville one each. From *puerperal fever*, Brooklyn, Pittsburg and Milwaukee one each. Seventy-six cases of small-pox were reported in Pittsburg, 60 in Cincinnati, eight in Brooklyn, five in Holyoke, four in Baltimore, two in Lawrence. Diphtheria 21 cases, typhoid fever nine, scarlet fever six, in Boston; diphtheria 11 cases, typhoid fever four, in Providence; diphtheria eight, scarlet fever seven, in Milwaukee.

In 33 cities and towns of Massachusetts, with a population of 955,443 (population of the State 1,783,086), the total death-rate for the week was 19.55, against 20.69 and 21.61 for the previous two weeks.

For the week ending December 31, in 149 German cities and towns, with an estimated population of 7,864,667, the death-rate was 22.7. Deaths reported 3427; under five 1591; pulmonary consumption 490; acute diseases of the respiratory organs 258, diphtheria and croup 195, diarrheal diseases 123, scar-

let fever 113, whooping-cough 59, typhoid fever 50, measles and 1 röteln 42, puerperal fever 20. The death-rates ranged from 12.9 in Potsdam to 33.8 in Erfurt; Königsberg 29.5; Breslau 22.5; Munich 26; Dresden 18.9; Berlin 25; Leipzig 17.8; Hamburg 23.5; Hanover 14.8; Bremen 16.9; Cologne 22.3; Frankfurt 16.7; Strasburg 28.1.

For the week ending December 31, in the 21 chief towns of Switzerland, population 479,934, there were 23 deaths from pulmonary consumption, acute diseases of respiratory organs 22, diarrheal diseases seven, diphtheria and croup five, whooping-cough five, typhoid fever two, puerperal fever one, scarlet fever one. The death-rates were, Geneva 19.7; Zurich —; Basle 19.3; Berne 23.4.

For the week ending December 10th, in the same towns, there were 32 deaths from pulmonary consumption, acute diseases of the respiratory organs 26, diarrheal diseases 13, whooping-cough nine, diphtheria and croup five, typhoid fever two, measles one. The death-rates were, Geneva 20.5; Zurich 22.3; Basle 15.1; Berne 18.7.

The meteorological record for the week ending December 24th, in Boston, was as follows:—

| Date.               | Baromet-<br>eter. | Thermom-<br>eter. |       |          |          | Relative<br>Humidity. |            |             |       | Direction of<br>Wind. |            |             | Velocity of<br>Wind. |            |             | State of<br>Weather. <sup>1</sup> |            |             | Rainfall.                |                      |

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 24, 1881, TO DECEMBER 30, 1881.

SUMMERS, JOHN E., lieutenant-colonel and surgeon, medical director, Department of the Platte. The leave of absence granted him in paragraph 6 S. O. 123, Department of the Platte, December 1, 1881, is extended one month, S. O. 135 Military Division of the Missouri, December 28, 1881.

HAYARD, V., captain and assistant surgeon. Now en route from Fort Davis to San Antonio, Texas, assigned to temporary duty at headquarters, Department of Texas, and to report to the medical director for instructions. S. O. 154, Department of Texas, December 12, 1881.

RAYMOND, HENRY L., first lieutenant and assistant surgeon. Relieved temporarily from duty at Alcatraz Island, Cal., and to report to the commanding officer of the Presidio of San Francisco for duty at that post. S. O. 214, Military Division of the Pacific and Department of California, December 9, 1881.

CORRECTION.—In the necrology of the Suffolk District Medical Society, in the JOURNAL of December 29th, the name of Dr. Spafford should be omitted. Dr. Cahill resided in Lynn, not in Salem. In addition should have been noted the deaths of J. P. Foley, of Fitchburg, September 18th, aged forty one, H. P. Phillips, of North Adams, November 24th, aged seventy-four, J. G. Thomas, of Worcester, November 29th, aged thirty-five.

MASSACHUSETTS COLLEGE OF PHARMACY.—The regular monthly pharmaceutical meeting of the College will be held at 7.30 P. M., on Tuesday, January 10, 1882, in the College Hall, No. 1151 Washington Street. William W. Bartlett, Ph. G., will

read a paper upon Pepsin, Methods of Preparation and of Assaying. All persons interested in pharmacy and collateral pursuits are invited to be present.

DR. B. F. DAVENPORT, *Registrar*.

BOOKS AND PAMPHLETS RECEIVED.—A Manual of Organic Materia Medica, being a Guide to Materia Medica of the Vegetable and Animal Kingdoms, for the Use of Students, Druggists, Pharmacists, and Physicians. By John M. Maisch, Ph.D., Professor of Materia Medica and Botany in the Philadelphia College of Pharmacy. With many Illustrations on Wood. Philadelphia: Henry C. Lea's Son & Co., 1882.

Student's Aid Series. Aids to Diagnosis. Part III. What to Ask. By J. M.ner Fothergill, M. D., M. R. C. P. New York: G. P. Putnam's Sons.

Suppression of Urine. Clinical Descriptions and Analysis of Symptoms. By E. P. Fowler, M. D. Ninety-three Clinical Cases, with Illustrations, Tables, and Diagrams. New York: William Wood & Co., 1881.

A Manual of Midwifery. By Alfred Meadows, M. D. Lond., F. R. C. P., assisted by Albert Venn, M. D., M. R. C. P. The Fourth Edition, revised and enlarged and illustrated with one hundred and thirty-seven Wood Engravings. New York: G. P. Putnam's Sons, 1882.

A Study of the Tumors of the Bladder, with Original Contributions and Drawings. By Alexander W. Stein, M. D., Surgeon to Charity Hospital, Genito-Urinary and Venereal Division. New York: William Wood & Co., 1881.

Transactions of the American Dermatological Association, with the President's Address, at the Fifth Annual Meeting, Newport, R. I. Official Report of the Proceedings. By the Secretary, Dr. Arthur Van Harlingen. Chicago. 1881.

The Hygiene of the Eye. An Address to Physicians. By Charles A. Oliver, A. M., M. D. Read before the Northern Medical Association, October 28, 1881. (Reprint.)

## Original Articles.

HEATON'S OPERATION FOR THE RADICAL CURE OF HERNIA.<sup>1</sup>

BY GEORGE W. GAY, M. D.,  
Surgeon to the Boston City Hospital.

THE Heaton method of treating inguinal hernia for a radical cure consists in moistening the fibrous tissues of the inguinal canal and rings with a preparation of white oak bark, and applying pressure by means of a compress and bandage to keep the canal closed, and prevent the descent of the hernia until the contracted tissues become strong enough to support the strain imposed upon them. The originator of the treatment claimed that by this method of "tendinous irritation" a permanent contraction of the fibrous structures was produced, which resulted in a lasting cure of the affection.

The fluid recommended for injection is composed of fourteen grains of the solid extract of white oak bark thoroughly rubbed up with half an ounce of the fluid extract of the same drug by the aid of gentle heat. The mixture is thick and muddy, and requires thorough shaking before using.

The operation is performed as follows: The hernia having been reduced, and the sac also, if possible, an instrument, resembling the hypodermic syringe, charged with the astringent, is thrust directly down through the skin into the external abdominal ring, and the point of the needle carried up the inguinal canal in front of the spermatic cord to the internal ring. The fluid is deposited slowly while withdrawing the instrument, the point of which is to be moved about in all directions, in order that the astringent may be distributed as evenly as possible throughout the canal. A compress and bandage are applied at once, and worn for a few weeks, when, in the successful cases, the rupture is cured, and requires no further support.

Twenty-four hours after the operation there is usually present some effusion and tenderness in the inguinal region at the seat of injection. The former may remain for an indefinite period, the latter commonly subsides in a few days, except in those unfortunate cases which terminate in suppuration. In some instances no thickening or effusion can be detected after the operation, while in other cases complete absorption of the exudation takes place after a time, and the parts return to their former condition. At the end of a fortnight, in the favorable cases, when the patient is allowed to leave the bed, the external ring will be found much reduced in size, and it is with difficulty that the finger can be introduced into the canal, where, previous to the operation, it passed easily.

Should any of the fluid be allowed to escape into the areolar structure outside the canal it is apt to produce a mass of induration in the loose tissues, which may persist for some time, but which, from its location, size, mobility, and gradual absorption, can seldom serve in any degree to prevent the hernia from coming down. Furthermore, cellulitis and abscess may result from this cause. Suppuration occurred in two of our patients. The abscesses were deep-seated, apparently extending through the anterior wall of the inguinal canal. The resulting infiltration entirely disappeared

in a few weeks after the abscesses closed, and in one case the hernia returned. These complications increase the suffering, prolong convalescence, and, in our opinion, add nothing to the success of the operation.

Dr. Davenport, who edited Dr. Heaton's book, and who was a careful and conscientious observer, always strongly insisted to the writer upon the importance of setting up only a very moderate local action by the injection; anything like severe inflammation was to be avoided if possible. He believed that white oak bark had a mild yet persistent astringent effect upon fibrous tissues, which was more lasting and less violent than that resulting from ordinary inflammation. Hence it is the fibrous and not the cellular structures which require the application of the astringent.

Where is the fluid deposited in this operation?

This is an inquiry that has often been made, but to which, in the absence of any examination upon the cadaver, it is difficult to give a satisfactory answer. Theoretically it should bathe the fibrous structures in contact with the neck of the sac. Practically, the surgeon, depending largely upon his anatomical knowledge of the parts, carries the needle up to the vicinity of the internal ring, and slowly empties the syringe during its withdrawal. Whether the sac is penetrated or not is probably largely a matter of luck rather than of skill, for in cases of old hernia it would seem hardly practicable to guide a needle between the sac and walls of the canal without penetrating one or the other. In some cases the needle moves about in the canal with great freedom, giving one the impression that it has entered the cavity of the peritoneum; yet in twenty-seven operations I have never seen anything like peritonitis. With few exceptions there has been only a moderate local disturbance, which did not require treatment, and which subsided in a few days. Although the pain of the operation is not severe, yet in children an anæsthetic is required to prevent the struggling and straining from forcing out the contents of the rupture before the bandage is applied; timid and nervous people also need it to enable them to keep still. Opiates are not usually called for during the after-treatment.

Below will be found a brief report of *all* the cases operated upon by me, both in hospital and private practice, with the exception of two, which have been under treatment but a few weeks. The results are stated as fully as possible, and no patient is reported *cured* who has not remained well for at least a year after discarding all support to the rupture.

CASE I. A waiter, aged twenty-four years, entered the hospital suffering from an inguinal hernia of moderate size on the left side; a truss had been worn. September 9, 1877, the patient was etherized, rupture reduced, and ten drops of the Heaton mixture injected into the inguinal canal. A compress and bandage were applied, and the patient remained in bed two weeks. He was discharged, wearing a bandage, at the end of five weeks. The external ring had been reduced to one half its former size by the operation, and the rupture had not returned.

CASE II. A sailor, thirty-four years of age, with a reducible inguinal rupture of seven months' duration, was operated on at the same time, and in the same manner as the previous case. He was discharged in four weeks, wearing a truss; the ring was contracted somewhat, but not sufficiently to control the hernia.

CASE III. A harness maker, aged forty-five, subject

<sup>1</sup> Read before the surgical section of the Suffolk District Medical Society, November 19, 1881.

to asthma and bronchitis, had a right inguinal hernia of some years' duration; the ring was large, and rupture uncontrolled by a truss. Operation June 10, 1878. Although the size of the ring was somewhat reduced, the intestine came down during an attack of severe coughing, and he was discharged not relieved.

CASE IV. A policeman had an ommental rupture of two years' duration, which extended half way to the bottom of the scrotum, and could not be controlled by a truss. The operation by injection was performed twice in as many months, with the result of reducing the ring to the size of a pipe stem, but a strand of the omentum still came down, though it could easily be kept up by a truss. Being very anxious to obtain a radical cure, he afterward submitted to an operation for the removal of the protruding omentum, but with only a partial success. He is now wearing a truss.

CASE V. A boy, a year and a half old, with a double inguinal hernia, was operated upon in 1878, in the out-patient department of the hospital. The after-treatment was neglected, as the mother failed to bring him back to have the bandage readjusted. The operation did no good, and the child now wears a truss.

CASE VI. James, twenty-one months old, right inguinal hernia; injected with three drops of the oak bark; wore bandage only a week; remained well at the end of fourteen months.

CASE VII. Michael, two and a half years of age, had a right inguinal hernia which had lasted six months; the ring was large, and two operations were performed. Three years later the rupture came down, only after great straining; he had worn no support.<sup>1</sup> It seems fair to consider him much relieved by the injection.

CASE VIII. A house painter, aged twenty-four, subject to convulsions, was injected for an inguinal rupture. The fits returned three days after the operation, when he jumped out of bed, pulled off his bandage, and the rupture returned. No benefit was received from the operation.

CASE IX. Daniel, aged twelve, a thin, spare boy, had a scrotal hernia with large rings, and loose pillars. Was injected twice within two months. He remains well at the present time, and has not worn a support for nearly two years.

CASE X. A boy, four years of age, was operated upon for an ommental hernia running into the scrotum, with little if any relief.

CASE XI. John, six years old, inguinal rupture, which had come down only a few times; it was reduced under ether about a week before the operation by injection. The ring was small, and hence peculiarly adapted to this operation. The little fellow was running about in a week, and has had no return of his rupture. It is now nearly two years since the operation. This patient would very probably have recovered by wearing a well-fitting truss.

CASE XII. For a year Miss —, aged thirty-eight years, had suffered a good deal from an ommental hernia, which came down into the right labium in spite of any truss she could apply. The operation was performed as in the male, and she remained in bed about a month. The resulting inflammation in this, as in all the cases narrated thus far, was very moderate, never threatening suppuration. She wore an abdominal supporter for several weeks. Fourteen months after the operation she remained well.

CASE XIII. A man, fifty-eight years of age, en-

tered the hospital, suffering from the early symptoms of strangulation of an inguinal hernia. It was reduced under ether, and the operation for a radical cure performed some weeks later. When he left the hospital, at the end of three weeks, the hernia had not returned, and the little finger could not be passed into the external ring. As the rupture was intestinal the operation promises to be successful.

CASE XIV. A baby, ten months old, was brought to me with double inguinal hernia, which trusses did not keep in place. Both were operated upon for the first time over a year ago; as the child has since had measles and whooping cough without bringing down the left rupture, we may safely call that one cured. Suppuration followed the injection upon the right side, and the operation has been repeated twice without success. The rings are large, the inguinal canal is short, and thus far no truss has been found to control the hernia. The operation is to be repeated after the child has fully recovered from whooping cough.

CASE XV. Mr. F., aged twenty-three, suffered a good deal from inguinal hernia, which could not be controlled by trusses. The rings were large, pillars thin, and abdomen flat. Both ruptures were operated upon without ether a year ago. Large effusion followed the injection, resulting in an abscess on each side, which was a long time in closing. Neither hernia has returned; the patient wears a double truss, and has been greatly relieved by the operation.

#### RECAPITULATION.

Number of patients 15; cured 4; relieved 8; not relieved 3. Number of ruptures 18; cured 5; relieved 8; not relieved 5. Number of operations 23.

With two exceptions the above cases seemed to be favorable ones for the operation. That it was not more successful may very likely be due, in part, to the lack of skill and experience in the operator; in part to the imperfect after-treatment, especially in several instances, occurring in the out-patient department of the hospital; and finally to the fact that a second operation could not be obtained in several cases, in which not quite sufficient contraction resulted from the first.

While I do not feel justified from my limited experience, extending over only four years, in expressing a decided opinion as to the real value of the oak bark treatment of hernia, yet my impression is that in the inguinal variety of the affection it is often a good method, and is worthy of further trial and study at the hands of competent surgeons. It would seem peculiarly adapted to cases with small rings, and to cases occurring in children, when Nature herself is making a constant effort to correct the deformity, and requires but little assistance to enable her to accomplish the result.

I know nothing of the merits of the operation in other kinds of hernia; but in the one under consideration I can but conclude that it is safe; it is not very painful; it is not very difficult to perform; it does little harm, even if it does no good; it will cure a certain number, and will relieve others.

---

— In a recent case in England the opinion was given that a surgeon who attended a duel to prevent a man from dying was to be held equally guilty with the person who fired the shot, because by his mere presence he forwarded the duel.

<sup>1</sup> I have lately repeated the operation upon this child.

A PENETRATING PISTOL-WOUND OF THE BRAIN.<sup>1</sup>

BY J. FOSTER BUSH, M. D. (HARV.)

G. B., a stout German lad, sixteen years old, weighing one hundred and sixty pounds, had always been well, previous to receiving the injury about to be described.

On June 29th, while playing with a younger companion, the patient was shot in the head, and immediately fell to the ground insensible. I saw him within ten minutes after receipt of the injury. He was lying upon a sofa, breathing heavily, with a slow pulse, the mouth drawn to the left and the left arm and leg paralyzed. It was with difficulty that he could be roused.

Upon examination a small round wound, with inverted edges, was found in the forehead, above the centre of the right eye and an inch above the eyebrow. Blood was oozing from the wound. Without the use of force, simply by its own weight, a probe passed into the wound, penetrated backwards to the depth of two inches. The opening in the skin was then enlarged so as to admit the tip of the little finger, and with this a circular hole could be felt in the skull. Further interference was deemed unwise, and the patient was put to bed, cloths wet in ice-water applied to the head, and the wound dressed with a two and a half per cent. solution of carbolic acid.

Two hours after the receipt of the injury he became perfectly unconscious, and could not be roused. Both pupils were dilated, the right fixed, the left responding to light. Later in the day, five hours after the receipt of the injury, Dr. H. H. A. Beach saw the patient in consultation. His condition was about the same as when last seen, the only new symptom being vomiting. Cerebral substance in masses as large as a split pea were noticed coming away with the blood. Upon examining the opening in the skull with a probe, small particles of lead were removed. Dr. Beach concurred in the opinion that non-interference was the best course to pursue. Absolute quiet and rest were enjoined; liquid diet in small quantities ordered; dry cold, in the form of an ice-cap, was applied in the place of the wet compresses; and a one per cent. solution of phenyle was used in place of the carbolic dressing.

The next day, June 30th, the pulse was 90, the temperature 101.2° F., the tongue coated, and the mind sluggish, but he would respond when spoken to. He complained of pain in the head, which was intensified by motion. Vomiting occurred at intervals. The right pupil was largely dilated and did not respond to light. He stated that he could not see out of his right eye. Ten grains of bromide of potassium were given every three hours.

On July 2d, attempts having been made for two days to obtain an action of the bowels, rhubarb powder, jalap, and scammony, and castor oil having been given without any effect, the desired result was finally brought about by a large injection of warm water, molasses, and olive oil.

On July 3d there was a sero-purulent discharge from the wound, the pulse was 100, the temperature was 102.4° F., and the pain in the head was increasing. The wound was oedematous and its mouth was covered by a slough; a flaxseed-meal poultice was therefore substituted for the phenyle, for twenty-four hours, after which it was discontinued, the wound having cleared up, and the phenyle was again resorted to.

<sup>1</sup> Read before the Surgical Section of the Suffolk District Medical Society, November 19, 1881.

On July 5th, one week from the time he was shot, the headache was of periodic character, and was only noticed over the right side of the forehead. With the right eye he could now just distinguish objects, but could not see clearly, things appearing as if seen through a mist. A two-grain pill of bisulphate of quinine was given every four hours.

On July 8th sight in the right eye was perfect, the headache was slight and local. For the first time since the accident he felt hungry.

On July 10th the seat of the cephalalgia changed from the front to the back part of the head. Up to this day the slightest motion of the head caused pain and nausea, but on this morning movement produced neither. The bromide of potassium was discontinued.

I have previously stated there was hemiplegia; there was loss of both motion and sensation, and the skin of this side was colder than the other. Upon tickling the sole of the left foot the right leg would be drawn up. He also experienced spasmodic pain from left hip to the heel, and was able to move the leg, for the first time since the receipt of the injury. The right pupil was still not so sensitive to light as the left, and the mouth not so much drawn to the left as before. Flannel bandages were applied from the toes to the hip of the affected side, and five-grain doses of the iodide of potassium were given three times a day, in place of the quinine. From this time on his condition was such that I will not continue to give the dates. He gained in strength constantly, relished his food and, if he kept quiet, felt nicely. It was forty-one days from the time of the accident before he could move his arm, and up to this time he could not sit up in bed without experiencing nausea, or feeling as if "something was rolling about in his head."

The bowels were regular after the first ten days, and at that time micturition ceased to be difficult. In seven weeks he was able to be taken in a hack a distance of three miles. The journey was well borne, the only discomfort being nausea just after starting, but as soon as he became accustomed to the motion of the carriage the sickness subsided.

Now, four months after the injury, he has no cerebral symptoms, the paralysis has disappeared, save in the flexors and extensors of the hand, but there is yet little strength in the muscles of the arm and leg, so that he cannot walk far, for fear of falling; he creeps about the floor, and even goes up and down stairs on his hands and knees. He can walk when any one supports him.<sup>2</sup> His appetite is good and he is especially fond of fruit, which was not the case previously. For a long time his sleep was accompanied with disagreeable dreams, and he would wake up screaming and frightened. The skin, which up to quite recently was cold and clammy, has now become warm and natural. The highest pulse was 100, and the thermometer never showed a temperature higher than 102.4° F. There is hyperaesthesia of the skin of the affected side. The tongue deviates slightly to the left, and both pupils are still dilated. Vertigo, at first, was a marked symptom. Now he experiences none of it, and can look from a height to the ground without feeling the slightest dizziness. There is loss of memory.

Although the symptoms and progress have been

<sup>2</sup> It is seven months since the receipt of injury and the patient now has perfect use of both the arm and the leg of the side which was affected. He can walk without any support, and has complete control of the muscles of the arm and hand.

favorable, and there are now no alarming circumstances, I do not feel that we can give a favorable prognosis, for although wounds in the anterior and upper portion of the hemispheres are least dangerous, yet the risk of continued cerebral symptoms, epilepsy, abscess of the brain, and death from acute cerebral disease are great. A case somewhat similar to mine happened some years ago in Vineland, N. J., which created quite a sensation at the time. The patient apparently recovered, but eventually died suddenly with cerebral symptoms, and after death a large abscess, with the ball in the centre, was found in the brain.<sup>1</sup> Concerning gun-shot wounds of the cranium where penetration has taken place and the ball has remained within, a recent writer<sup>2</sup> has said, "The foreign body never becomes a harmless tenant, its presence always furnishes a potential source of mischief, and recovery can only be held to take place in a limited sense, for notwithstanding the absence of symptoms speedy dissolution may ensue with little or no warning."

In some cases of apparent recovery where foreign bodies have remained in the brain the patient did well till cerebral excitement was experienced. In several cases spoken of in Holmes, "Five died suddenly after excessive drinking, one by the excitement produced by playing cards, and one on account of a slight injury received upon the head."

In the second surgical volume of the Medical and Surgical History of the War of the Rebellion, there are found reports of one hundred and eighty-six cases of balls penetrating the cranial cavity, of which number one hundred and one were fatal. In eighty-five cases of removal of the foreign body there were forty-three recoveries. In one hundred and one cases in which the foreign body was not removed fifty-nine were fatal.

The same authority under the head of Balls Lodged within the Cranium gives nineteen cases in detail, the analysis of which shows that they were nearly all more or less troubled in after life, or rather, as long as they were kept under observation, which was in all the cases at least ten years. Of the nineteen cases, two were subject to epilepsy, four affected with marked vertigo, four with other cerebral symptoms, in one no report covering the subsequent history is given, one was paralyzed, one had continuous pain in the head, in one the wound had not healed, and concerning four there were no bad symptoms recorded.

In another series of four hundred and eighty-six recorded cases of penetrating gun-shot wounds of the skull four hundred and two died, sixty-five were discharged from service, and nineteen were returned to duty.

The weapon which was used in this case was the oft-mentioned "toy pistol," of the "Magic" pattern, and is only intended for blank cartridges to be used simply for explosion, but in this case it was loaded with a shell carrying a number twenty-two conical projectile. The distance between the boys at the time of firing was twenty-one feet.

— Nearly one twelfth of the Esquimaux inhabitants of the Labrador coast have been carried off by an epidemic which appears to be a malignant type of measles.

## A CASE OF CRIMINAL ABORTION RESULTING IN DEATH FROM AIR-EMBOLISM.

REPORTED BY W. W. GANNETT, M. D.

ALTHOUGH death from criminal abortion is by no means uncommon, ample opportunity being afforded the medical jurist for observation of the pathological processes by which death is brought about, yet it must be conceded as rare for the fatal result to be produced by the entrance of air into the circulation through opened uterine sinuses.

The rarity of cases of air-embolism from a pathological point of view, together with their greater rarity from a medico-legal stand-point, coupled also with the fact that the medical examiner was enabled indirectly to bring about the conviction of an abortionist, lends interest to the case given below, both to the pathologist and medical jurist.

It has long been known as a fact in surgery that wounding of veins in the region of the neck was an extremely dangerous accident, from the liability of air being sucked in by the action of respiration and its accumulation in the heart; death usually ensuing instantaneously. More recently it was discovered that pregnant, parturient, and puerperal women were liable to a similar catastrophe, the factors requisite to produce such a result being open uterine sinuses in communication with air. Position of the woman was also considered of importance, the knee-elbow being the most favorable to the entrance of air into the uterus, from the negative pressure produced by the weight of the abdominal viscera acting in the opposite direction to that either in the dorsal or erect positions. Again, cases of death from air-embolism have been observed to follow intra-uterine injections in the puerperal condition, air gaining entrance into the uterus with the infecting fluid, either through carelessness of the operator or defect in the instrument used.

The history of the case to be at present considered is as follows: An unmarried mulatto woman, twenty-one years old, whose health, previous to January, 1881, had been good, consulted in that month an irregular practitioner living in Boston for some indefinite symptoms, among which backache was prominent. This doctor examined her, said she had prolapse and retroflexion of the womb, and gave her medicine. A few months later she again saw him, this time on account of suppression of the menses; for this he gave her some drug. At a visit in June he suspected, from the continued absence of menstruation, that she might be pregnant; finding on examination that this was the case he charged her with it, and, on her confessing the whole affair, advised her to take legal measures to recover from the father. Four months later, on the 26th October, she went with a sister to this doctor's office by appointment, the object being, as stated by the girl to her sister, that as she was in trouble she was going to have something done, and that Dr. T. was going to do it. Immediately on their arrival the girl went into a small room with the doctor, the sister remaining in the office. After being in this room about fifteen minutes, during which he was two or three times interrupted by callers at the outside door, this doctor suddenly rushed out of the small room, saying that the girl had fainted, and asking the sister to come in. He worked over her a few minutes, sent for a physician, who arrived shortly after, but she was already dead.

Medical Examiner Draper was summoned, and on his

<sup>1</sup> Gross.

<sup>2</sup> Holmes' System of Surgery: Am. Ed.

reaching the house Dr. T. stated to him that he supposed the case to be one of heart disease; that he had made no examination whatever; that he was simply sitting beside the patient on the bed, when she suddenly threw up her arms, uttered a moan, and fell backwards in a convulsion, from which all efforts to resuscitate her were of no avail. It may be here stated that the girl's drawers, which had been previously removed, were replaced by Dr. T. after her death. On the following day an autopsy was made by Dr. Draper, his report of which is as follows:—

External examination. The body was that of a well-nourished, apparently healthy, colored woman. Rigidity of limbs was well marked. There were patches of livid discoloration in the posterior parts of the body, on the sides of the neck and chest, and in the loins. There was no odor or other sign of decomposition.

Upon the posterior or lower parts of the external genitals and upon the buttocks were stains of blood.

Red stains, resembling blood stains in their appearance, were found upon the underclothing removed from the body at the time of the autopsy.

Internal examination: When the primary incision was made from the neck along the front of the body to the genitals, bubbles of air were observed to issue from the blood-vessels in the parts over the breast bone. The right side of the heart was fully inflated with air; and when a small puncture was made in this distended side of the heart air escaped, at first in a free jet, then in the form of bloody bubbles, and the walls of the heart collapsed. The left side of the heart was firmly contracted and empty. The structure of the organ was entirely healthy. The superficial veins of the heart were seen to contain air as well as blood. The blood in all parts of the body was thin and of a dark color; there were no clots.

Both lungs contained an excess of blood. In other respects they showed no change from a healthy condition.

The spleen was normal in size, color, and consistency.

The kidneys were engorged with blood, and were larger than natural, but their structure presented no indication of disease.

The liver was healthy. Bubbles escaped from the mouths of the vessels when the organ was cut.

The stomach was of natural appearance. It contained between half a pint and a pint of partially digested food taken (by estimate) within three hours before death.

The intestines were healthy. The veins leading from them were seen to contain air as well as blood.

The brain and its membranes presented nothing remarkable except the presence of air in the vessels.

The lower region of the abdomen was occupied by the enlarged womb and its contents. The highest point of the womb was about two inches above the navel. Its color was natural throughout its anterior portions, but the posterior and lateral regions were reddened. The various sinuses in the walls of the organ were fully inflated with air, and stood out from the surface as tortuous elevations distributed in all directions. The left lateral region of the cavity of the womb was felt to contain air outside the sac holding the child. The enlarged vein on the left side of the organ contained air, with blood.

The womb, lower intestine, bladder, and vagina were removed together from the body, and upon dissection the following appearances were disclosed:—

The vagina was five inches long. Its lining membrane was white, thickened, and rough. Its calibre was very little, if any, in excess of that of the vagina of an unimpregnated woman. There was a little staining of a reddish thin fluid along the posterior wall.

At the anterior part of the external opening of the vagina there was a bruise-discoloration half an inch long and one eighth of an inch wide at its widest, the ends of the bruise being more deeply discolored than the middle part.

The womb was ten and a half inches in length and eight inches wide (outside measurement). The entrance to its cavity was opened to an unusual degree, admitting the thumb easily. The margin of this opening showed the effects of recent irritation by some foreign body. Just within the entrance, the membrane lining the cervical canal was reddened; and at the upper part of this canal on its posterior surface was a reddened area three eighths of an inch long and one quarter of an inch wide.

The cavity of the womb contained a child enveloped in its membranous sac and surrounded by its natural fluid. This child was a female, of light color, and well developed; it measured fourteen inches in length and weighed two pounds; its hair and nails were well grown; there was no bony centre in the lower end of the thigh bone.

The membranes enveloping the child had been forcibly separated before death from the left lateral region of the inner surface of the womb, so that fully one half of that surface was denuded and between it and the membranes there was air and a small quantity of liquid blood. This denuded area was reddened in all directions and was in marked contrast with the paler surface left by the separation of the remainder of the membranous adhesions at the time of the autopsy. Along the posterior portion of the inner surface of the womb, in the middle line of that region, the discoloration was much deeper, presenting an area of bruised and roughened uterine tissue five inches long and in width from half an inch (at its lower extremity) to one inch and a half (at its upper end). A less defined but distinct region of bruised and reddened uterine tissue was found a little to the right of that described and extending upward, like that, from the upper end of the cervical canal.

In various parts of that region of the womb which had been denuded of the membranes before death, the open mouths of many of the venous sinuses in the walls of the organ were seen and were further demonstrated with the blow-pipe; air could freely enter these openings and thence pass into the general circulation.

The bladder was empty and healthy.

The ovaries were well-developed. The right ovary contained a corpus luteum.

In conclusion Dr. Draper states as his opinion, that the said individual came to her death by the admission of air into her blood-vessels and heart through ruptured venous sinuses in the walls of her impregnated womb, in consequence of the introduction of a blunt instrument into the cavity of the womb.

An inquest was held later, and Dr. T. was indicted on the charge of attempting to procure a criminal abortion. In default of twenty thousand dollars bail he was remitted to jail to await trial.

At this trial, which occurred in December, the facts above stated were brought out. The remainder of the

testimony was that of the medical experts, and it not only constitutes the part of most interest to physicians, but it was of most importance in the case from a legal stand-point.

Medical Examiner Draper testified to what has already been mentioned in connection with the view and the autopsy, and gave also in his direct examination a very clear account of what is known of air embolism in general, and its special application in this case. His testimony may be summarized as follows:—

Admission of air into veins is a very serious accident. The effect of air so admitted varies according to the amount; if large, and its introduction rapid, death immediately follows; if small, or the introduction be slow, only a temporary circulatory disturbance, as shown by the fainting and distress, may result. The amount of air and its manner of introduction can be determined by a post-mortem examination, provided such examination be made soon after death, before decomposition has developed gases. If death follows rapidly after the introduction of air, the right side of the heart would be fully inflated with air, with comparatively few bloody bubbles; if the fatal result were slower the right cavities would still be expanded, but the contents might consist almost wholly of bloody bubbles, from the churning action of the heart. Instant death has resulted from entrance of air through the uterine sinuses in delivery at term and in instrumentally induced abortion. The anatomical structure of the uterus is such that under favoring circumstances air can enter rapidly and in large quantities into the uterine sinuses, and so make its way to the heart. Such favoring circumstances are: an open cervical canal; a separation of the fetal membranes, exposing orifices of uterine sinuses; unusually large sinuses; imperfect plugging of sinuses by clots; the structure of the canals themselves, being intimately adherent to the wall of the uterus so that they remain open when divided.

Dr. Draper then explained the way in which death is brought about in such cases. When the external air has free entrance to the cavity of the uterus, either through a tube like a catheter, or by being forced with a syringe, or by admission through the natural passages, and when the orifices of the uterine sinuses are open, then the uterus, alternately contracting and expanding under any stimulus (a foreign body like the air itself), will act like a rubber bulb to suck into its cavity and into its sinuses this external air, while the heart and lungs meanwhile act also as a suction force to draw air through the veins leading from the uterus to the heart; its rapid accumulation in the right side of the heart distends these cavities instantly, so that the heart's muscle becomes paralyzed and unable to contract. Whatever blood mingled with air the heart can propel goes to the lungs, and from the bubbles of air lodging in the capillaries the pulmonary circulation is seriously interfered with. A convulsion with this form of death is the rule. Death may result instantly, where the amount of air is large, by paralysis of the heart and asphyxia, or it may result from the consecutive effects of the air, as a pneumonia; this in cases where only a smaller quantity enters the circulation.

In regard to the case at issue Dr. Draper further testified that the autopsy showed all the anatomical conditions to be favorable to the rapid entrance of a large amount of air by way of the uterine veins to the heart; that the passages to the uterus were open, the fetal membranes had been separated from the inner

surface of the uterus, over half its area, and the orifices of the sinuses were thus exposed; very little hemorrhage had occurred to plug these orifices with clots; the sinuses were larger than usual. In addition the autopsy showed, as a matter of fact, that air had been admitted to the cavity of the uterus, to the sinuses, to the uterine veins and inferior vena cava, and to the heart itself.

The amount of air and its distribution as found at the autopsy were wholly incompatible with the theory that any considerable time had elapsed between the entrance of air to the heart and the death of the patient.

The post-mortem examination of the body was made so soon after death that sufficient time had not elapsed for any decomposition to have developed,—indeed, the deeper parts of the abdominal cavity were still warm; the heart was inflated by air without odor, and not by the fetid gas of decomposition. There was not the slightest odor or appearance of putrefaction about any part of the body.

The wounds observed on the inner surface of the uterus were recent; they might have been and probably were made immediately before death; they could not have been made so long as twenty-four hours before death.

The separation of the fetal membranes from the uterine surface was not a natural, spontaneous result of the normal action of the uterus, because if it had been the separation would have been in a transverse direction near the cervix, and not in a longitudinal direction involving fully one half the inner surface of the organ. Moreover, bruising could not result from a natural process, but the reddening would have been uniform.

The bruises on the orifice of the vagina, on the os, in the cervical canal, and on the inner surface of the uterus all indicate the introduction of a blunt instrument into the cavity of the uterus.

The small amount of blood found and its fluid condition indicate the suddenness of the death after the injuries which set the blood free.

The witness further stated it to be his opinion that the deceased could not herself have produced the appearances found in the uterus by the introduction of an instrument in her own hand, for the reasons that she could not pass an elastic instrument into her vagina through the os and up the posterior wall of the uterus to a depth of at least ten inches so as to separate the membranes as they were found; further, that she could not pass an inelastic instrument into her uterus without doing much more damage than the autopsy disclosed to the tissues of the os, cervical canal, and inner surface of uterus. The chances are decidedly in favor of the view that with either an elastic or stiff instrument, if no other injury were done, she would have ruptured the fetal membranes, and let out the fluid within. Again, death resulted too suddenly to be accounted for on the hypothesis of the self-infliction of the injuries found.

The operation was done by some person other than the deceased and was done just before death.

Knowledge of the pregnant condition of the woman being admitted by the person accused, the purpose of the operation was to induce miscarriage and that only.

Dr. Draper's cross-examination lasted four hours, but failed to shake him in the least, in his testimony.

Dr. W. L. Richardson testified, that the pelvic organs of the woman had been brought to him a few hours after the autopsy; that he examined them and,

as a consequence, believed that the individual came to her death from the introduction of air into the circulation. He further corroborated the testimony of Dr. Draper in all particulars.

The defendant, Dr. T., testified, among other matters, that he had made a digital examination of the woman and that it was during this examination that she fell back in a convulsion. This is in direct contradiction to the statement made to Dr. Draper at the view, at which time he stated that he had made no examination whatever. Defendant further testified that the object of this examination was simply to touch the os to determine whether there were any ulcerations about it, and that, with the exception of his finger, he introduced nothing into the vagina or uterus of this woman.

The experts for the defense, Drs. H. G. Clark and H. M. Jernegan, agreed with Drs. Draper and Richardson that death could only have resulted from air embolism, but differed from them in supposing it to be possible for the individual to have carried about in her uterus a certain amount of air, for a period varying from a few hours to two or three days; that either this air, in consequence of its gradual expansion by the heat of the body, separated the membranes from the uterine surface, thus opening the uterine sinuses and so gained entrance to the circulation; or, that as a result of some slight irritation, like that of the finger touching the os, the uterus suddenly contracted on this mass of air contained within its cavity and that the forcibly compressed air tore away the membranes and so entered the circulation. As to the method by which the air originally entered the uterus, it was thought by the experts for the defense that it might have been the result of a douche, for cleansing purposes, either improperly given or else from a leaky syringe, in the hands of the woman herself.

To sum up the case; both sides agreed that death resulted from air embolism. The defense maintained that the air did not enter the uterus from any measures taken by Dr. T.; that it was already in the uterus at the time she came to his office, and that the innocent digital examination was enough to make it explode, as it were, and enter the circulation; and further, the fact that air was found in the veins beyond the heart was evidence that the air had entered the circulation slowly, and that death must have been gradual. The prosecution declared that the various steps in the whole series, from the separation of the membranes to the death of the individual, must have followed one another rapidly, occupying in all less than five minutes, and that said separation must have been done by an instrument in the hands of the accused, in his office, immediately before her death.

The judge, in his charge to the jury, stated that they could not find a verdict of guilty unless the government had proved that the child was alive at the time of the attempted abortion.<sup>1</sup> This is a question of considerable importance from a medico-legal point of view, from the fact that it is impossible for the pathologist to determine in many cases whether a child in the dead mother's uterus was alive or not at the time the mother died. The District Attorney is authority for the statement, that the opinion of the highest English courts, is a contrary one.

The jury returned a verdict, in three hours, of guilty.

## RECENT PROGRESS IN OBSTETRICS.

BY W. L. RICHARDSON, M. D.

### PUERPERAL HAMATOCELE.

Dr. R. SOMERVILLE reports<sup>2</sup> two cases of this rare complication of the puerperal state. In the first case the effusion was in the septum between the vagina and the rectum, while in the second case it was in one of the labia. The mechanism of the production of the hemorrhage would seem to have been that in the first place the pressure of the child exerted on the upper part of the vessels prevents the free return of the blood, and so causes them to become turgid. In the second place, owing to the descent of the fetus, pressure of a severe kind is also made on the distended part of the vessel or vessels, thus causing a rupture. Finally, when this pressure is removed free hemorrhage from the ruptured vein or veins occurs, and this will go on until the tension of the effused blood equals that of the blood inside of the vessel. Fortunately, the pressure restraining the hemorrhage is not usually taken off until after the child is born, and therefore the development of the hamatocele is delayed until after the labor is concluded. If, however, the pains cease, or there are long intermissions, and the fetus recedes, and pressure is removed, then the bleeding will occur before birth, and may seriously interfere with the labor.

As regards treatment, Dr. Somerville advises that whenever the hamatocele is developed after the termination of the labor, the pain should be soothed by opiates. Then, where practicable, a pad of some soft material should be applied, that its support may do something to prevent a rupture of the thrombus, and the consequent danger of an increased hamorrhage. After the tumor has ceased to enlarge, and when there is a likelihood of the injured vessels being sealed up, it is a question whether the tumor should be at once incised or not. Dr. Somerville decidedly favors waiting as long as possible, with a view of avoiding the danger of that peculiar sensibility which all puerperal women have to septic influences.

In cases where the hamatocele develops during the progress of the labor, immediate delivery is the safest course, for by waiting the swelling may become a most serious obstruction to the passage of the child, and the thrombus is liable at any moment to burst, giving rise to a frightful hamorrhage.

### ELECTRICITY IN OBSTETRIC PRACTICE.

Dr. G. Apostoli reports<sup>2</sup> that during the last two years he has been in the habit of using the electric current in his obstetric practice, with a view of hastening the completion of the involution of the uterus. Immediately after delivery an induced current is applied to the uterus, and its intensity is gradually increased. The application is made from eight to ten times during the first six days after the termination of a natural labor. If the labor has been premature or an abortion has taken place, the application of the electricity is made from fifteen to twenty times. He is convinced that this method of applying electricity has yielded most marked and favorable results.

<sup>1</sup> We have reason to believe that his honor has subsequently modified this opinion. — Ed.

<sup>2</sup> Edinburgh Medical Journal, July, 1881.

<sup>2</sup> Annales de Gynécologie, May, 1881.

## MANAGEMENT OF THE THIRD STAGE OF LABOR.

Dr. Kabischeke gives an account<sup>1</sup> of the method in which the third stage of labor is conducted in Professor Freund's obstetrical clinique at Strasburg. It is there considered that the expulsion of the placenta is just as much a physiological process as the expulsion of the child, and therefore it should be left to nature, and not hurried, as has of late become the custom, owing to the teaching of Credé. By waiting the membranes are more perfectly separated from the uterine wall. There is much less danger from hæmorrhage than where the uterus is immediately forcibly compressed. In the majority of cases the spontaneous expulsion of the placenta takes place within three hours, and then the vagina is washed out with a five per cent. solution of carbolic acid. A wad of jute steeped in the carbolic solution is applied to the vulva. During the convalescence no vaginal or uterine injections are used. Where there is a threatening of post-partum hæmorrhage the hand is kept over the fundus of the uterus so as to follow its contractions, but if there is no sign of bleeding the uterus is left alone. The case is watched for from an hour to an hour and a half, and if no bleeding has yet taken place the expulsion of the placenta is left to nature. If necessity demands the immediate removal of the placenta Credé's method is adopted. If any portion of the membranes or placenta is left behind it is removed by the hand, and the uterus washed out with a two per cent. carbolic solution. In these cases the vagina is washed out three times daily with the same solution during the whole period of the convalescence.

## CLINICAL OBSERVATIONS ON PUERPERAL TEMPERATURE.

Dr. A. D. L. Napier gives the following summary<sup>2</sup> of four papers which he has contributed on the above subject:—

(1.) Temperature varies in the normal puerperal condition from 97° F. to 99.5° F. The average for three or four days succeeding parturition is 98.5° F. to 99° F. The healthy puerperal range is 2.5° F.

(2.) No temperature over 99° F. is normal after four days. The healthy patient may have an *occasional* night temperature of 100° F. or 101° F. within the first four or five days, but a continuing, or even a morning record like this requires explanation.

(3.) Slight causes, for example, constipation, retention of urine, etc., give a rise to 99° F. to 100.5° F., sometimes more.

(4.) Retention of clots or secundines, 99° F. to 101° F. or upwards, 103° F. at times.

(5.) Woid has a sudden late temperature of 103.5 F. with rapid pulse; the heat falls quickly with the development of the local affection. Other cases of mastitis are mildly febrile for several days.

(6.) Metritis (endo- and peri-) gives record of 103.5° F. with slow pulse.

(7.) Peritonitis has a single rigor, and a sudden early temperature of 101° F. or upwards; the pulse is wiry. General peritonitis, if severe, 105.5° F. to 106° F.

(8.) Pelvic cellulitis, oöphoritis, parametritis, etc., have a heat of 101° F. to 102.5° F.; the pulse is weak and irritable. Recurrent rigors mark fresh deposits of pus, and are followed by temporary increased heat, 101.5° F.

(9.) Pyæmia and uterine phlebitis average 103° F., perhaps more. Cases in which the veins are rapidly affected are soon 104.5° F. to 106° F., and end speedily. Pyæmia is frequently late in development, seven to ten days.

(10.) Septicæmia varies from 102.5° F. to 107° F. The heat is never less, at least for some period of the twenty-four hours, than 102.5° F. There is no security from remission till the night temperature is under 100° F. Recovery may take place after 106° F., but is rare.

(11.) Mental emotion may show 104° F. or even 106° F., and we may sometimes have in addition symptoms resembling metro-peritonitis. These cases do not persist, and are generally normal in less than forty-eight hours.

(12.) If the temperature does not rise within ten days from delivery there is little risk of grave disease unless from imprudence in exposure to cold or zymotic influences.

(13.) Although the temperature is moderately low, 100° F. to 101° F., so long as the pulse continues 120 or more we are not safe from relapse; no anxiety need be felt so long as the temperature is kept under 102° F. However fast the pulse, if the temperature is low the prognosis is favorable, except of course where the lowness of the temperature is due to a collapse. If the temperature is persistent at 102° F. or frequently recurs to this point there must be an abnormal organic condition.

(14.) Temperature should be observed night and morning for the first seven days, and daily for three to seven days after, more especially if instrumentation has been required for delivery, or if zymotic or epidemic disease prevails. When an abnormal temperature prevails it should be reduced to normal as early as possible. It is of the highest moment to bring it down to 100° F. and keep it there or lower.

## PELVIC ARTICULATIONS.

Dr. Korsch (St. Petersburg) reports<sup>3</sup> the results of a series of experimental investigations made by him with reference to the mobility of the pelvic articulations. The measurements were made by means of dilators so constructed that not only the extent of the separation of the two blades was measured but also the amount of the force required to separate them. This dilator he applied to various parts of the pelvis of the bodies of recently-delivered women, of pregnant women, and non-pregnant women, and men. The following results were arrived at: (1.) During pregnancy and in patients who have large ovarian or uterine tumors there is a widening of the diameters of the pelvis. (2.) At the inlet the greatest widening is that which occurs in the transverse diameter; while at the outlet the antero-posterior diameter is increased. (3.) Nearly twice as much force is required to increase the diameter of the inlet as to change that of the outlet. (4.) Whenever the transverse diameter of the inlet is widened, there is a shortening of the antero-posterior diameter; but an increase in the antero-posterior diameter does not affect the transverse measurement. (5.) Even if the transverse diameter of the brim be lengthened to its maximum, the conjugate may still be further extended; but the transverse diameter cannot be altered after the maximum length of the conjugate has been reached. (6.) If the transverse and antero-poste-

<sup>1</sup> Centralblatt für Gynäkologie, 1881, No. 7.

<sup>3</sup> Zeitschrift für Geburtshülfe u. Gynäkologie, 1881.

rior diameters of the inlet are increased simultaneously the amount of increase in each is not so much as when either is alone extended. (7.) Widening of the outlet slightly diminishes the conjugate, while the transverse diameter of the brim remains either unaffected or is slightly lengthened. (8.) If the inlet is widened the reverse is true. (9.) On the average the greatest amount of mobility is in the sacro-iliac synchondrosis. (10.) The amount of synovial fluid was increased in those joints where mobility was most noticeable. (11.) Any increase of the antero-posterior diameters depends upon the movements of the sacrum; while that of the transverse measurements is due to a yielding of the symphysis pubis. (12.) Any increase in the size of the synovial cavity of the pubic articulation leads to a greater mobility of the joint. (13.) The mobility of the pelvic articulations does not depend on the previous number of deliveries.

## Reports of Societies.

### PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, SECRETARY PRO TEM.

SPECIAL MEETING, DECEMBER 27, 1881. In calling the Society to order, the President said:—

This unusual meeting is held that the Society may take such action as shall seem fit to honor the memory of one of its oldest and most distinguished members, Dr. Edward Reynolds, who died on Sunday last, at the age of eighty-eight years.

Identified, socially and professionally, with a generation which is fast passing away, the younger men of this Society will recall the stately presence and genial manner of Dr. Reynolds in this hall, but a short time ago, when with unabated strength and animation he interested large audiences by his charming reminiscences of by-gone medical men who had practiced in this vicinity.

Founder of one of the noblest charities of Boston, the Eye and Ear Infirmary; distinguished as an ophthalmologist in the days when there were no specialists; actively engaged in medical teaching up to a comparatively recent period; holding fast to all the best interests of the profession, he retained the universal esteem of his medical brethren throughout his long career. This Society will therefore gladly show by its action the respect which the example of a life like that of Dr. Reynolds so richly deserves.

Dr. H. W. WILLIAMS offered the following resolutions:—

*Resolved*, That this Society deeply regrets the loss it has sustained in the death of Dr. Edward Reynolds, as one exemplifying in his own character and practice all the noblest traditions of our profession.

None who knew him could forget the dignified urbanity of his manners, or fail to note his extensive acquirements, or doubt the heartiness of his friendship. Among the many distinguished men of his generation he held a foremost place as a diligent student and admirable teacher, an honorable and courteous confidant, and a judicious, faithful, and sympathetic practitioner—uniting all the qualities which could make him highly esteemed as a physician, as a citizen, and as a friend.

Retaining until nearly fourscore and ten years the fresh geniality of his youth, and the ripe wisdom of his

manhood, his presence was always welcome, and his life an example to us all.

*Resolved*, That while we feel that he rests from his labors but his good works abide with us, we tender to the family of Dr. Reynolds our sincerest sympathies in their bereavement.

Dr. D. H. STORER spoke as follows:—

Mr. President,—In rising to second these just and appropriate resolutions, as the oldest professional associate of our deceased brother, I would add a few very brief remarks. For more than half of a century I enjoyed the privilege of an uninterrupted intimacy with Dr. Reynolds. I knew him well, and admired him. He was a true man; his character was irreproachable.

For many years, until increasing infirmities compelled him to withdraw from the duties of his calling, he stood in the front rank of the profession. He was endeared to an extensive circle of friends by his sympathy and kindness and fidelity in their hours of sorrow. He was esteemed by the entire profession for his courtesy, the liberality of his views, and his honorable bearing. His memory is worthy of our homage,—I rejoice that we have assembled to render it.

Dr. BETHUNE said that as a former colleague of Dr. Reynolds at the Eye and Ear Infirmary, he always preserved the most delightful recollection of their old association.

Dr. Reynolds was ever genial and charming in manner, and always ready and anxious to obviate difficulty and smooth the path of men younger than himself. His death will be felt acutely by all who in those days were in intimate and most friendly relations.

Dr. SHATTUCK spoke as follows:—

I thank you, Mr. President, for the opportunity of bearing testimony to the worth, kindness, and courtesy of our departed colleague. He had been a score of years in the profession when I commenced the practice, and his knowledge, skill, and success were widely recognized. He was an example of conscientiousness, fidelity to duty, kindness, and courtesy to all the younger brethren. His religious faith and belief were evident in his conduct and bearing. His success as a teacher in the Eye and Ear Infirmary and in the Tremont Medical School was well known.

Dr. John C. Warren, the Professor of Anatomy, having leave of absence for a year, Dr. Reynolds was called upon to assume his duties. In listening to the lectures of our present Professor, it may seem an easy matter to discourse upon that subject, so easily and with so little effort are they delivered. But to a busy practitioner of twenty-five years to acquire a sufficient familiarity with the innumerable details of anatomy, and with new truths and views in physiology is no slight task, and here Dr. Reynolds exhibited his intellectual powers and industry to the admiration of all for whom his work was done. With advancing age and infirmity he gradually laid aside his duties, and in his retirement his cheerfulness, courtesy, knowledge, and wisdom were still conspicuous. We all felt it a privilege to be in his company, and especially those of us who are growing old found much to learn in our intercourse with him during his last years. We part from him with regret. We shall miss his hearty greeting and his words of knowledge and experience, whilst we may regard his death as a happy one with such a record of a long life filled with good works, and leaving a memory to be cherished by all who knew him.

Dr. HOLMES said: My early recollections of Dr.

Reynolds go back to the time when he was a surgeon of the Eye and Ear Infirmary, where I with my fellow-students enjoyed the privilege of his instruction. But my more intimate relations with him began with the formation of the Tremont Medical School. This school owed its origin to the active mind and stirring energy of Dr. David Humphreys Storer. He succeeded in interesting Dr. Jacob Bigelow and Dr. Reynolds in the project, and I was subsequently added to the association. I may allude incidentally to the combination of elements which this school presented in my three colleagues. Dr. Bigelow shrewd, eminently practical, full of sagacious common sense; Dr. Reynolds genial, expansive, the best natured of men; Dr. Storer, — who will pardon, I trust, my use of his name, — enthusiastic, sometimes to incandescence, in defatigable in caring for the students, whom he looked upon almost as if they were his own children.

Dr. Reynolds would have harmonized less accordant natures than were here combined, by the charm of his presence and the infinite good nature which belonged to him. From the time I became his associate I have counted him as my friend, and have known him better than most of his professional brethren of a somewhat later period can have known him. I do not think his mental proportions were so generally recognized as was the majestic aspect of his bodily presentment. He was modest and sensitive, and few were aware of his varied accomplishments. He was best known to the profession and to the public as a practitioner in the specialty of diseases affecting the eye and ear, in which he, with Dr. Jeffries, was long the leading authority among us. But he was also a skilful surgeon, an esteemed physician, and a most acceptable teacher. He had a natural artistic turn which most persons knew nothing of. I have never forgotten a drawing of his, shown in a popular lecture, illustrating the way in which corpulent persons, in their instinctive efforts to preserve the centre of gravity, are supposed to be strutting in the complacency of self-admiration. He kept his scholarly tendencies, also, rather in the background. He once took a fancy for learning the German language, which was little known or studied in this community at the time. He began with Faust and a German dictionary, and made a complete translation of the poem as his first essay. His conversation was full of interesting recollections and anecdotes. One could hardly meet him and go away without retaining not only the after-glow of his hearty greeting, but the remembrance of some story, some quaint saying, illuminated by a beaming smile or emphasised with a cheery laugh, — some personal impression that stamped the moment into a medallion of memory.

My last visits to Dr. Reynolds, within the present year, have left a delightful record of themselves in my recollections. The infirmity of his far advanced years betrayed itself in many ways, but rarely has any human figure illustrated more strikingly that fine expression of Wordsworth,

"The monumental pomp of age,"

once happily applied, as I well remember, by Mr. Winthrop, to the late President Quincy. The failure of the organ of hearing, the maladies of which he had so often remedied in others, rendered sustained conversation with him somewhat difficult. But it was pleasant enough to listen to his reminiscences of men and things as they were in the past, and to his larger dis-

course on those deeper themes which old men love to talk of as voyagers approaching their harbor to speak of the land to which they are drawing near. Always a man of strong religious feelings and convictions, he rested in the faith of the fathers like a ship which rides quietly at anchor, and lets the fleets bound for unexplored regions sail by where their own charts and compasses may direct them. The portion of the Book of Books which came nearest and remained dearest to him, as the scenes of earth faded from his sight, was the Gospel of St. John. It was the one fullest of tenderness; "Love one another" was its precept and its spirit. Age is blessed in many ways in the midst of its trials, — most of all, perhaps, that it so often brings with it the divine gift of charity, that apostolic charity which suffereth long and is kind. If it seems sometimes that age endureth all things, it also hopeth all things, always trusting that its own kind impulses come from a fountain of infinite love. So has this venerated friend, our elder brother, been gently called away from us, dying in peace and hope at the happiest season of the Christian year, and leaving with us an honored name and a precious memory.

Dr. H. I. Bowditch followed, saying: —

Mr. President, — I am glad that you ask me to say a few words in reference to our deceased associate. Yet I can scarcely add anything to what Dr. Holmes has uttered. In one respect, however, Dr. Reynolds was peculiar. I have never met one in our profession of a more joyous disposition. It continued bright even to the last moments of life. He could have no sympathy with that morbid disposition which leads many of our youths to question, "Is life worth living?"

In 1834 or 1835, when I had just returned from student life in Europe, and I daily plodded around on foot in search of patients, he often invited me to take the vacant seat in his chaise in which he was making his professional calls. This was always a signal for me to be sure of listening to a fund of anecdotes, which kept us both full of boisterous laughter as he rather carelessly drove along the streets. Meanwhile his horse would fall into a sluggish gait and often almost come to a stand-still, while we two seemed, to passers-by, like persons quite forgetful of that dignity which should have been preserved by people engaged in the quiet duties of the medical profession. I wish we had many such in our profession now; but I know of none to take his place. His hilarity arose from his happy, contented nature, and it spread sunshine on all who met him. It continued to the last. It was most delightfully shown to me a few weeks only since. When I called at his house I found him in his chamber sitting in his chair as he might have been often in former days. He arose with but little effort, and extending his hand to me with the old bright smile I had been long accustomed to, said: "Well Dr., you have come to see how pleasant it is to grow old." He then commenced a series of remarks like the following: "I found myself happy in having no patients, for I do not want them." "I can't walk about much, but I enjoy keeping still." His mind was as clear as ever, and he seemed to enjoy showing to me all the various pleasures of growing old. He could enjoy a laugh, execute one as easily as formerly; and now, as we learn that in the last few days he was beginning to lose this charm, I cannot help sympathizing with Bryant in his *Old Man's Funeral*. Dr. Reynolds has left as beautiful an example of cheerfulness under all circumstances — an

example that cannot now be lost, at least by all those who knew and loved him. Permit me, as most appropriate to this occasion, and as expressing my own thoughts better than I could were I to speak longer, to read a few lines from the poem above alluded to:—

"His youth was innocent; his ripper age  
Marked with some act of goodness every day;  
And watched by eyes that loved him, calm and sage,  
Faded his late declining years away.  
Cheerful he gave his being up, and went  
To share the holy rest that waits a life well spent.

"That life was happy; every day he gave  
Thanks for the fair existence that was his;  
For a sick fancy made him not her slave,  
To mock him with her phantom miseries.  
No chronic tortures racked his aged limb,  
For luxury and sloth had nourished none for him.

"And I am glad that he has lived thus long,  
And glad that he has gone to his reward;  
Nor deem that kindly nature did him wrong,  
Softly to disengage the vital cord.  
When his weak hand grew palsied, and his eye  
Dark with the mists of age, it was his time to die."

DR. C. J. BLAKE spoke as follows:—

It is but just and meet that in behalf of the gentlemen constituting the Board of Surgeons of the Massachusetts Charitable Eye and Ear Infirmary, whom I have the honor to represent on this occasion, a sincere and earnest tribute should be paid to the memory of the man who fifty-seven years ago founded the institution whose professional benefits it is our privilege to now administer. The spirit which animated Dr. Reynolds in the inception of this institution, and his early labors in its behalf, is well evidenced in his address to the patrons of the Infirmary, delivered, at the dedication of the building at present occupied, in 1850.

In November, 1824, Dr. Reynolds, in connection with Dr. John Jeffries, established the first gratuitous clinic in this city. Furnished with limited means, and commencing with a single room, the benefits conferred by their labors were nevertheless strikingly apparent. Eighteen months later, at a meeting convened for the purpose, a report of their proceedings was considered, and so impressed were those present with the humanity and success of the enterprise that a subscription was at once undertaken to give it permanency.

To Dr. Reynolds and Dr. Jeffries alone, therefore, is due the credit of having, unaided, first discovered and then so well supplied a need as to entitle them to the right to demand the generous continuance of its relief.

In March, 1826, at a meeting of subscribers the institution was regularly organized under the name of the Boston Eye Infirmary, and a board of managers appointed. In February of the following year it was incorporated by the legislature of the State as the Massachusetts Charitable Eye and Ear Infirmary.

During the following ten years its location was thrice changed, the last removal being to the Gore Mansion House in Green Street, where, with increased accommodations and facilities, it not only enlarged its sphere of usefulness to the suffering, but threw open its doors to medical students, and established a course of lectures. For fourteen years the institution continued its good work in Green Street, the number of its patients steadily increasing until, in 1850, nearly twenty-five thousand patients had received relief. Before this date it was found indispensable to again increase its capacity, the State and private individuals again came to its support, and in 1850 the present building in Charles Street was ready for occupation. Recently

the building has of need been further enlarged, and now nearly ten thousand patients annually reap the benefits of a clinic which has been uninterruptedly continued since, with an earnest faith in the perpetual value of good works, it was first opened by Dr. Reynolds.

The resolutions were adopted, and it was voted that they be entered on the Records, and a copy sent to the family of Dr. Reynolds.

Adjourned.

#### PROCEEDINGS OF THE SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, M. D., SECRETARY PRO TEM.

NOVEMBER 19, 1881. DR. R. M. HODGES in the chair.

DR. GEORGE W. GAY read a paper entitled

#### HEATON'S OPERATION FOR THE RADICAL CURE OF INGUINAL HERNIA.

Vide page 25 of the JOURNAL.

DR. D. W. CHEEVER, in opening the discussion, spoke as follows:—

"I have operated two or three times by Heaton's method without much success. I have also done Wood's operation many times with varying results. I have brought the pillars of the ring together by subcutaneous sutures, both wire and catgut, and have cut down upon the rings and sewed them up, as well as closed them after herniotomy for strangulation. None of these operations answered the requirements in all cases. The essence of success consists in setting up peritonitis in the sac, and in the ability to control the inflammation when started. As long as the external ring is merely closed by adhesions, the serous canal remains open, and the same causes acting may reproduce the hernia. Wood's operation seems to me unphilosophical, since it aims to draw together the pillars of the ring, structures which are firm, fibrous, and immovable, yet the site is more favorable for this operation in inguinal than in femoral hernia, for the borders of the ring are more flexible. When I first did Wood's operation Dr. J. B. S. Jackson, who was present, asked me if I was sure that I was going to obliterate the serous canal. I have come to believe that this is essential to the cure of hernia, and the obliteration can only be accomplished by peritonitis. In children, if they are not too fat, it is possible, by a little manipulation, to lodge the point of the syringe in the inguinal canal, and produce so-called tendinous irritation, that is, the exudation of plastic material between the cord and the inner borders of the ring. This was accomplished in the ancient cure by the hot iron, castration being followed by a canterization of the cut ends of the cord and vessels. Wood's operation is somewhat dangerous, first, from the burrowing of pus into the iliac fossa; second, from pyæmia. Heaton's method, so far as our experience goes, seems safe. But inasmuch as its success depends on a peritonitis being set up in the sac, I do not see how the possible danger of lighting up a general peritonitis can be avoided. The chance of cure by this operation is better in children and young persons, but it must be remembered that some children are cured by wearing trusses if they are well applied, and kept in position for a long time: one descent of the hernia, however, will undo all that may have been gained in months.

"On the whole we may conclude that when a truss has failed to cure, and the child has reached the age of about six years, this is the best time to operate. Injections can be tried first, this failing I should resort to sutures or blister and cauterization, followed by a truss. Wood's flat box-wood *horse-shoe pad* truss is an extremely valuable adjunct to a cure. It avoids dilating the ring as conical pads do, exercises flat and firm pressure over the inner ring, and leaves room for the cord to escape pressure by a slot."

Dr. H. J. BIGELOW followed:—

"The operation under discussion was comparatively new when I commenced the practice of surgery; at that time the operation was held as a secret by Dr. Heaton, who was censured by the Society for his course in this respect. Although it was not known exactly what the injection was, it varied at different times; being sometimes white oak bark, sometimes a solution of tartrized antimony, tincture of iodine, or an essential oil, in fact anything that would produce irritation. Enough time has elapsed to enable us to judge of its merits. The testimony is of two sorts: First, cases of which we have knowledge personally. Of this class I have known several patients with large inguinal hernia, who have been benefited by the operation to this extent, that whereas before the hernia could not be controlled by a truss, it afterwards could. I think in one of these cases the mental influence of the operation had a certain effect; however, the patient was more comfortable, and we must give the operation the credit of it. The second class of testimony is that given by the truss makers. They say that as a rule the majority of hernia considered as cured by this operation return after a lapse of one or two years. I formerly tried Heaton's method, and did not find it satisfactory.

"In discussing this question we should look at the theory as well as the practice of the operation. Whenever the tendon of the abdomen is open, whether from injury or otherwise, there we may have a hernia. If we plug up this opening with plastic material that may suffice for a time, but plastic lymph is always absorbed, and when absorbed the hernia is liable to return. Practically I could never feel certain where the injection went, although if it does not go into the sac itself the irritation may produce enough exudation to occlude the ring for a time. But when the lymph is absorbed the old condition tends to re-establish itself. The difficulty is to find an efficient substitute for the deficient tendinous material.

"When Wood's operation came along I tried it several times, but never could see how drawing the pillars together could make them adhere permanently under great pressure. Wood, in his book, pays great attention to minor details, such as the character of the knot, but that is not the main question. I do not think that the operation has met with the success in other surgeons' hands that Wood claimed for it in his own. In former years cures were effected in young subjects by the long-continued wearing of a hard pad, the irritation produced by this causing an exudation of lymph which plugged the ring, while the tendinous opening was gradually reduced in size.

"I operated some time since on a large strangulated umbilical hernia in rather a new way, with complete success." (The case here reported was published in the JOURNAL of January 5th.)

Dr. E. H. BRADFORD mentioned a case operated on by Heaton's method, with rather an unfortunate re-

sult. A laboring man entered the out-patient department at the City Hospital with a reducible inguinal hernia. The hernia was reduced, Heaton's operation performed, a pad and bandage applied, and the man sent home. He returned the next day, having removed the bandage in the mean time, with a return of the hernia. Dr. Bradford could not reduce it, and advised the patient to enter the hospital. This advice was not followed, however, and the termination of the case was unknown to the speaker. Dr. Bradford thought the operation should never be done unless the patient was under absolute control.

Dr. GAY said he had never operated on out-patients unless children in arms. It was most important to keep the patient from walking. Dr. Gay had heard from Dr. Robert F. Weir, of New York, that he had operated thirty times by this method, with eight cures, although he thought hardly enough time had elapsed to consider the cure absolute. Dr. W. F. Bull had also operated about thirty times, but was not ready to report results. Dr. Weir thinks if the patient can be entirely under his control one half of the children or of those with small rings can be cured. Dr. Gay tells patients they can perhaps be cured, that the operation will require two or three weeks of absolute rest, and may have to be repeated. He considered a patient cured if the hernia had not returned at the end of a year; this time, perhaps, was too short, but it seemed to him fair.

Dr. T. DWIGHT asked if in any cases there had been any inflammation, either sympathetic or otherwise, of the testis.

Dr. GAY replied that he had not met with it. Dr. Bull had seen orchitis in one case.

Dr. POST asked if the results seemed better in those cases where the injection had seemed to enter a cavity, and therefore presumably the sac of the hernia.

Dr. GAY thought not, but his experience was not yet large enough to say definitely.

Dr. HODGES, in closing the discussion, said that he thought it strange in the very community where the operation originated there were so few cases seen where it was claimed a cure had been effected. He remembered several cases shown as cured at one of the medical societies some years since; one of these persons in returning home the same evening slipped down stairs, and reproduced the hernia.

Dr. J. F. BUSH read a paper entitled

#### A PISTOL WOUND OF THE BRAIN.

Vide page 27.

Dr. T. DWIGHT opened the discussion, and spoke as follows:—

I imagine the first thought which occurs to a practitioner when called to a case of this nature is, 'Where is the ball?' Our principal guide in deciding this point is the location of the paralysis. Dr. Lucas Championnière has recently published a book, giving rules for locating the injury by the symptoms. The difficulty is, however, that we cannot tell if they are the direct result of a lesion or of irritation of the brain substance. The results of physiological investigations on this point are still so uncertain that localization of functions in the brain cannot as yet offer any very trustworthy guide to the surgeon. I think it would be profitable to have all cases of wounds by toy pistols reported, the number seems so large.

Dr. C. D. HOMANS said that during the past summer many of this class of wounds had been treated at

the City Hospital. In one case where the ball was supposed to have penetrated the forehead, it afterwards descended into the eyelid, and was removed, it having lodged in the frontal sinus.

Dr. CHEEVER reported two cases of head injury.

First. A girl, six years old, while sitting in a swing, was accidentally shot in the centre of the forehead by some boys who were firing at a mark. The child walked to the house, but soon became unconscious. When seen air was bubbling in and out of the wound, showing that the frontal sinus was opened. Ether was given, and the wound enlarged; the front wall of the sinus being shattered, several pieces of bone were extracted, and the posterior wall of the sinus was then also found to be shattered, as well as both tables. The fragments of bone were cleared away, and the membranes came into view, showing a wound about the centre of the hemispheres. A probe was carefully introduced three inches, but nothing was felt. No farther interference was deemed advisable, and in a comparatively short time the wound was entirely healed. For some time the girl suffered from severe headaches, but now, six years after the injury, her health seems perfect.

The second case was that of a little girl, aged five years, who was shot in the *meatus auditorius* by a drunken father, the pistol being held very near. Complete facial hemiplegia ensued. There was very considerable suppurative, but no severe cerebral symptoms. The wound healed well, but the hemiplegia and a persistent carache remained. Five years after I was called to her again. She seemed very healthy, but the hemiplegia was present. Her mother had sent for me on account of a sore throat, but a short time previously an abscess in the tonsil had opened spontaneously, and the bullet had been discharged from it.

Dr. C. D. HOMANS mentioned a case of a girl treated at the City Hospital for bullet wound of the brain. The missile was never found. Recovery was speedy and complete.

Dr. HODGES thought the number of recoveries from penetrating wounds of the brain suggested the thought that a patient was safer with a bullet in his brain if let alone than he was if endeavors were made to ascertain its locality, and remove it. This is practically hopeless, and therein lies the secret of the large percentage of recoveries.

#### A NEW STEAM SPRAY.

Dr. J. C. WARREN exhibited a new steam spray having a number of useful modifications. One of the disadvantages of most sprays is the time consumed in getting up steam. This is obviated by only a very small amount of water being in the boiler, which is fed by a pump from two reservoirs, these as well as the boiler being heated by the lamp; thus water can be gradually introduced into the boiler without stopping the spray. Another advantage is the absence of the usual bottle for the antiseptic solution; this is contained in a reservoir at the base of the instrument, a glass window being introduced through which the amount present can be seen. There are two spray points, either of which can be shut off by a lateral movement; they have also a vertical movement. Spray was obtained from cold water in less than two minutes.

Dr. GAY spoke of the apparatus in use at the City Hospital, where a rubber pipe is connected with the steam pipes in the house. It works admirably.

Dr. Gay showed the kidneys from a child ten years of age; the history of the case is as follows:—

The child, being frightened, jumped out of a bathtub, and fell on the edge of a wooden pail, striking on her left side between the last rib and hip. A physician was not summoned till the following day, hematuria was then present, but gradually disappeared; peritonitis set in; tympanites, vomiting, pain, and sleeplessness were the principal symptoms. Rectal nutrition was resorted to, but it was very difficult to nourish the child. After two weeks the pus pointed in the left inguinal region; an incision was made, and drainage tube inserted about six inches. For some days there was a slight improvement, but she soon began to fail again. There was no evidence of blocked-up pus. Cutting down upon the kidney from behind was thought of, but abandoned on account of the extreme weakness of the patient. Death ensued two months after the injury.

At the autopsy the left kidney was found lying in a small pool of pus; the lower half of the organ had entirely disappeared; there was no extravasation around the kidney, and no bagging of pus, the opening to the groin being patent.

### THE HEALTH CONGRESS AT BRIGHTON.

#### SPECIAL REPORT FOR THE JOURNAL.

"LONDON-BY-THE-SEA" has recently been the seat of an important Congress of those interested in sanitary science, which convened on Tuesday, the 13th of December, and continued its sessions for a number of days following. The president was the distinguished Dr. Benjamin Ward Richardson, and the chairmen of the three sections, (1) health of towns, including sanitary legislation, (2) food in its connection with national and domestic economy, and (3) house sanitation, with its concomitant educational training, were respectively, Mr. Edwin Chadwick, C. B., Mr. John Robert Holland, M. A., M. P., and Dr. Alfred Carpenter. The proceedings were inaugurated on the 12th with the opening of a very complete sanitary exhibition at the Royal Pavilion, Brighton; on which occasion the chair was taken by the Earl of Chichester, Lord-Lieutenant of the County of Sussex, and there were present on the platform many persons of note, including Dr. Richardson, the Speaker, Mr. Brand, Mr. J. R. Holland, M. P., Sir Albert Sassoon, C. S. I., the Lord Bishop of Chichester, Sir Henry Cole, K. C. B., the Mayor of the city, and Mr. William Hamilton, with whom the scheme of the Congress took its rise. After the singing of God Save the Queen with fine effect by an immense choir composed of all the choral bodies in the town and district, and some religious exercises, the Earl of Chichester delivered the opening address, in which he remarked that those who imagined country houses to be exempt from the latent causes of disease which infect towns and cities were grievously in error. The germs of low fevers, he said, were as common in mansions as in hovels; and he instanced the dangerous illness of the Prince of Wales as a proof that even Royalty was not always shielded against pestilence by the precautions which science dictates. The Mayor of Brighton followed with a statement of particulars concerning the exhibition, and the Speaker, Mr. Brand, delivered the address of the day; which was brief and practical. One of the definitions that had been given of the present age, he remarked, was, that it is an age of great cities. The population of Great Britain was

increasing at the rate of a thousand daily, and this increase was taking place chiefly in London and the other great cities and towns. Brighton he considered to be setting a good example in holding this Congress, and in making necessary improvements throughout the town; but there remained much yet to be done for its sanitary condition, as the sight of the smoke-cloud which hung over it should remind them. This he held to be one of the greatest evils of growing cities. In London it had come to be nearly intolerable, and so it would be in this enormous seaside town, unless something were done to remove it. Next to the abatement of the smoke nuisance he valued the preservation of open spaces, and he had heard suggestions about a Brighton park which he hoped would meet with an assenting response. After a few remarks from Mr. Holland, M. P., Handel's Hallelujah Chorus was sung by the choir, and the exercises, which occupied only one hour altogether, were brought to a conclusion by the chairman finally declaring the exhibition open. The company then proceeded to inspect the array of classified objects in the temporary iron buildings adjoining the Dome, in the king's apartments of the Royal Pavilion, in the saloon, and in the Corn Exchange of the town. Added to the sanitary exhibition was a department of lighting, including all phases and systems of the electric light, and a department embracing a varied and curious display of horological instruments; while, lastly, there was a loan collection of decorative objects of great extent and value supplied by the South Kensington Museum.

The Congress itself was inaugurated on the evening of the 14th, when the President, Dr. Richardson, delivered an address in the presence of a distinguished company. His subject was the Seed-Time of Health, and he commenced by saying that in point of health the children of the present age were a reproach. He had never seen a perfectly healthy child, and it might safely be said that no one was born free from the taint of disease. It was these inherited defects which accounted in great measure for the enormous mortality which was found in juvenile life. The statistics which Dr. Richardson quoted showed that of every ten children born in England less than seven ever reached their twentieth year. It was a heavy percentage of child mortality, and a dread tax to be paid to the genius of hereditary or acquired disease. The statistics of some other nations were more alarming still. Thus, in France only one half of the children born reached the age twenty; while in Ireland the percentage of mortality was even greater. Dr. Richardson would have modern society converted to the Hellenic idea that immature death was a thing for which shame ought to be felt. "The gate of health," he continued, "is that which leads to the truly good in politics, art, science, letters,—ay, and religion. A long and perfect life can only be attained by perfection of life at its opening, in the seed-time of health." The perils environing ordinary mankind he described as two thirds inherited, accidental, inflicted, and acquired. The dangers from inheritance came in for his chief notice, and he was especially emphatic in his disapproval of what he termed "the inheritance of disease." He believed it was by carefully, earnestly, and perseveringly correcting the evils arising from the four influences referred to that the rising generation could be brought to the acquirement of successful and honorable vitality.

At present, he continued, we had not arrived at a scientific knowledge of what it is that constitutes such a disease as small-pox or scarlet fever. Vaccination or inoculation was merely a temporary expedient, adopted by medical art until the time came when we should be able to attack the very germs of such maladies. "Pure blood and a healthy life led in childhood and youth ought to banish the possibility of disease."

Dr. Richardson spoke strongly against corporal punishment in schools, contending that there was nothing more likely to injure the young both mentally and physically; and, after giving some very sound advice in regard to the proper care of infants and young children, concluded with an appeal to the people of Brighton to turn to a practical use in their own town the information which they would be able to derive from the proceedings of the Congress.

The actual proceedings of the Congress were opened on the morning of the 14th with an address by Mr. Edwin Chadwick, C. B., the chairman on the health of towns section, on the prevention of epidemics. He first detailed the measures taken with respect to the outbreaks of Asiatic cholera in 1848 and 1849, at which time he was the chief executive officer of the first general board of health. They found that the quarantine service as practiced on the continent as a defense was, like an attempt at shutting out the east wind, utterly futile and illusory. Although evidence pointed to the fact that great epidemics occurring at long intervals were chiefly climatic or affecting particular areas, they were also, as in the case of small-pox, largely communicable by infection. Speaking of the reasons which led to the abandonment of hospital treatment, he said that they found that in the stage of collapse in the disease the removal of the patients in many cases accelerated death, and that, on the whole, with all the defects of the houses where they lived and the difficulty of obtaining medical appliances in them, it was better to allow the sick to remain there. He strongly recommended frequent ablutions on the part of the people as a protection against epidemics, and also the appointment of experienced paid sanitary officers as the best means of economy. From the returns of the local government board he calculated that they had saved a quarter of a million of lives in the death-rate from infectious diseases.

The general conclusions that he arrived at were,—that cases of small-pox, typhus fever, and other zymotic diseases occurred in the greatest proportion in overcrowded, foul houses, deficient in water supply, and with bad drainage; and that the effective removal of these causes was to be striven after; and that when infectious diseases occurred, the best preventive treatment against their spreading would be effective home treatment, if possible, and otherwise by providing temporary accommodation, obviating the necessity of removing the sick to a distance, and the danger of aggregating such cases in large hospitals, which, he believed, tended to augment the death-rates.

Among the other papers read on this day was one by Dr. Mackey on The Geology and Climate of Brighton from a Health Point of View. The climate of Brighton, he said, resembled that of the best parts of France, and the mean winter night temperature was at least four degrees warmer than that of London. Referring to the climate in spring he observed that Sir James Clarke had doubtless set the fashion of forsaking Brighton at that time of year, and for some delicate

chests he thought the advice still good. In the summer the influence of the sea in equalizing the climate was apparent, and the freshness and coolness of the place was proverbial. Thus, in June the temperature of Brighton was no less than seven degrees cooler than that of Greenwich. Popular opinion was right, however, in pronouncing the autumn as the best season for Brighton.

In a paper on the correlation of public health and sanitary legislation, Dr. B. Browning, medical officer of health for Rotherhithe, gave a number of statistics to show that the sanitary improvements generally adopted throughout the county had resulted in a material advance in the public health.

A paper which elicited some interesting discussion was one on Reform in Slaughter-Houses, by Mr. H. F. Lester. After pointing out the evils attending the multiplicity of these places at present existing in London and other large towns, he advocated the establishment of public *abattoirs*, on the French pattern, in order to insure good sanitary arrangements, to prevent cattle being driven through the public streets, to render inspection of diseased meat more efficient, and to put a stop to cruelty. A model slaughter-house on improved principles, he thought, should be established, in order to introduce painless methods of killing, and to set an example of the most perfect structural and other arrangements possible. The chairman of the section, Mr. Chadwick, cordially indorsed these suggestions, from his own personal experience of the subject; as did also Dr. Richardson, who stated that he had often left off eating meat altogether for weeks on account of his disgust at what he had seen in private slaughter-houses.

In the evening a *soirée* for the members of the Congress was held by the mayor and mayoress of Brighton.

The session on Thursday, December 15th, was devoted to the section on food in relation to national and domestic economy, and the first address was that of the chairman, Mr. J. R. Holland, M. P. After stating that he would leave the discussion of the origin and chemical, physiological, and therapeutical character of food to scientific and medical men, he proceeded to speak of the production of food, its distribution, and its economic uses. In treating of the first head he deplored the fact that England was becoming less and less of a farm, and more of a meadow and playground, and quoted Lord Leicester and Mr. Lowe's opinion, that if the pastures of the United Kingdom were thoroughly drained and effectually farmed they would produce double the quantity of food that they did at present. He also mentioned Mr. Caird's view, which was opposed to this, and said that it was his own opinion that until the conditions under which land was held were modified, it was premature to speak of the limit of production being arrived at. In one particular, especially, he thought that the production of food might be materially increased and that was by more attention being devoted to rabbits, goats, and eggs, on which the peasantry of Belgium and France thrived so well.

With regard to the distribution of food, he pointed out that the comparatively small produce was hampered and filtered by the excessive charges of English railway companies, and contrasted this state of affairs with that existing in America and France. Coming to the third head, the speaker advocated the more general use of vegetable food, and deprecated the vast amount of material that was consumed in the production of

alcoholic drinks. In conclusion he strongly recommended the adoption of improved methods of cookery, by which food might be rendered so much more wholesome, as well as more economically used.

Dr. C. R. Drysdale, of London, read a paper on The Importance of Cheap Food to Longevity. He said that at the census of New Zealand it was lately found that the death-rate was as low as eleven and one fourth per thousand per annum, or not quite half the death-rate of London, twenty-three per thousand, or about one half that of England and Wales. The real cause of the low death-rate of New Zealand was not climate, for the richer classes in Great Britain had just as low a death-rate, eleven and one fourth per thousand; but he believed it was because the inhabitants of New Zealand were as a community so much better fed than the inhabitants of the United Kingdom, where the population pressed so severely upon the food supply.

Mr. A. F. Haleome followed with an address on New Zealand as a Source of Food Supply to Great Britain, and Miss Gates, of the National School of Cookery, read a paper on Bread Reform, in which she dwells on the relative qualities of white bread and wheat meal bread, and showed that the latter, while less expensive, contained far more nutriment than the former. Mr. Lightfoot's paper on The Preservation of Food by Cold, maintained that there need be no further difficulty in supplying all the demands that the country could put forth for cheap, wholesome, fresh food. Mr. Winter Blyth, medical officer for Marylebone, read a paper on Rational Feeding, in which he showed the necessity for modifying the kind and quantity of food according to the age, constitution, and habits of the individual; and Mr. Parker Rhodes read a paper on Water Reform, which pointed out the evils resulting from the use of hard water, even when used for the supply of steam engines.

On the morning of the 16th, the chairman of the section on domestic health, Dr. Alfred Carpenter, whom Dr. Richardson introduced as a well-known veteran in the cause of sanitation, delivered his address. Every individual, he thought, was entitled to live to the age of one hundred years, and if he did not, he was deprived of a portion of his birthright, either by his own act or by the acts of others. The conditions producing disease and death were, as a rule, of man's making, and could be removed by the action of man. Poisonous excreta were liable to exist in some shape or other in the blood, and they ought to be removed as rapidly as nature designed that they should be. Taking up the subject of want of ventilation in the homes of the people, he said that Dr. Farr had proved that mortality was progressive according to the extent of overcrowding; the influence of overcrowding being most fatal in its effects upon children under five. Such mortality was mainly caused by impure air, and it ought to be an established rule of architects in putting up buildings to provide entrances for fresh air as well as exits for foul air, which should be ample for the number of individuals likely to occupy the premises. Among the papers read afterwards were the following: The Prevention of Smoke, by the late Sir Antonio Brady (read by General Alexander); Home Sanitation, by Mr. H. H. Collins, secretary of the health department of the Social Science Association, who urged that more attention should be paid to drainage, ventilation, and cleanliness, and to the ques-

tion of dress; House Inspection, by Professor Fleeming Jenkin, advocating rigorous inspections by competent sanitary engineers; Hints on Domestic Sanitation, by Dr. Strong, of Croyden; Domestic Filtration, by Mr. E. Bailey Danton, who recommended the more general use of filters, especially in country houses, where the water was allowed to stand in tanks and become stagnant; The Aspect of Public Elementary Education in Relation to Health, by Mr. H. Stephens, F. C. S.; and Sanitation in Decoration, by Major Robert Edis, F. S. A.

In the evening a banquet was held in connection with the Congress, in the banquet hall of the Royal Pavilion; when the chair was occupied by Dr. Richardson supported by the Mayor of Brighton.

### Recent Literature.

*Rheumatism: Its Nature, its Pathology, and its Successful Treatment.* By T. J. MACLAGAN, M. D. London: Pickering & Co. 1881.

In November, 1874, Dr. MacLagan began to use salicin in the treatment of rheumatism. In March, 1876, he published some account of his experiences up to that date in the London *Lancet*.

Having been for some time convinced of the miasmatic origin of rheumatism, and being impressed with the action of quinine on the various forms of intermittent and remittent fever, and with the action of the cinchonacea generally on the diseases of tropical climates, it seemed to him that a remedy for rheumatism was most hopefully to be looked for among those plants and trees whose favorite habitat presented conditions analogous to those under which the rheumatic miasm seemed most to prevail.

Reflecting that a low-lying, damp locality, with a cold rather than a warm climate, are the conditions under which rheumatism is most likely to arise, and that the plants whose haunts best correspond to this description were those belonging to the natural order salicaceae, he had recourse to the bitter principle contained in the bark of many species of willow — salicin.

Almost at the same time that MacLagan published his results with salicin in England Stricker and Riess published theirs with salicylic acid, as manufactured from carbolic acid by Kolbe, in Germany.

The author's object in writing the present volume has mainly been to develop and expound his miasmatic theory of rheumatism, and to set forth at greater length his later views and experience in the use of salicin and the salicylic compounds in its treatment.

These are apparently but little modified from those to be found in his early articles.

After devoting a few short chapters to the duration, seat, and nature of rheumatism, the nature of the rheumatic poison is taken up. A long chapter is given to the lactic acid theory of rheumatism. Lactic acid the writer regards merely as an excess in the blood of a product of retrograde tissue metamorphosis, as an effect and not a cause; he therefore rejects it as the morbid agency which originates the disease, though recognizing its action and its share in the production of the phenomena of a rheumatic attack. The miasmatic theory of rheumatism is then taken up, and this, with a consideration of the nature and action of malarial, occupies several chapters in which the author's views

are well and ingeniously reasoned out. He considers it evident that the rheumatic poison, both in its history and in its effects on the system, bears a closer analogy to the poison of malarial fever than to any other morbid agency; sufficient grounds are advanced, he thinks, to show that there is reason to regard rheumatism as malarial in nature, and its poison as a miasm which enters the system from without.

The remaining chapters of the book are occupied with a consideration of the effects of the poison upon the various organs and tissues which it usually attacks; with some remarks upon the relation of rheumatism and chorea and upon rheumatic hyperpyrexia; and with the treatment of the disease. With patients who have had several previous attacks of rheumatism the writer has found potassic iodide a very useful, and often essential, supplement to the salicylic treatment, otherwise his confidence in and his success with that treatment seems unabated. In this we should say that his experience is rather more favorable than that of most other early enthusiasts. He finds salicin well borne in most of those cases where salicylic acid produces unpleasant symptoms, and expresses his belief that, as a rule, acute rheumatism is more severe as met with in private than in hospital practice.

Dr. MacLagan has written a candid and interesting book, to which we shall probably take occasion to refer again, and certainly has reasons to offer for his faith.

*A Text-Book of Practical Medicine with Particular Reference to Physiology and Pathological Anatomy.* By DR. FELIX VON NIEMEYER. Translated from the eighth German edition by special permission of the author. By GEORGE H. HUMPHREYS, M. D., and CHARLES E. HACKLEY, M. D. Revi-ed edition, two volumes. New York: D. Appleton & Co. 1881.

WHEN the last edition of the American translation of Niemeyer's *Lehrbuch der Speciellen Pathologie und Therapie* appeared in 1871, the original had already passed through eight editions in Germany. In that year Niemeyer died, and since his death his book has gone through another edition in Germany, edited by Dr. Eugene Seitz. Dr. Seitz made extensive changes in the text as well as inserted a large amount of new matter. In the present American edition the translators have reverted as nearly as possible to Niemeyer's original language, thinking that the style of the book had not been improved by Dr. Seitz's liberties with the text. They were doubtless wise in this, for few Germans would be likely to improve upon Niemeyer's style. At the same time the translators have drawn freely upon the new material incorporated in the last German edition, and have themselves made such additions from other sources as seemed to them calculated to render the work more useful to the American reader. Short articles have been inserted upon several subjects not treated of in the original, and a chapter has been added upon yellow fever.

A book made up in this way labors necessarily under many disadvantages, some of which were abundantly illustrated in a late edition of Reynold's *System of Medicine*; it is certainly not Niemeyer, nor has it on the other hand, some of the advantages of some of the best American text-books on the theory and practice of medicine.

In saying this we wish to be understood as criticising the inception, not the execution, of the present work.

**Medical and Surgical Journal.**

THURSDAY, JANUARY 12, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

**THE COLLECTIVE INVESTIGATION COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.**

THE amount of valuable information on various topics connected with medicine which might be furnished by the combined efforts of the physicians of so large a country as England, and which is now allowed to go to waste, is enormous. An effort for combined action in the preservation of such material was inaugurated at the Cambridge meeting of the British Medical Association two years ago by the appointment of a committee to organize a plan for carrying out such a work. The report of the committee giving the outline of the plan deserves notice on this side of the water.

The committee speak of the proposed work as capable of producing valuable results, yet as one which will require great and continuous effort to carry it on in an efficient and satisfactory manner. To combine a number of men in the systematic and careful observation and record of facts is difficult under any circumstances, and especially so in the case of medical men whose irregular and harassing avocations necessarily disincline them to enter upon and continue a labor of this kind.

It is obvious that success will much depend upon the energy, perseverance, ability, and judgment of the secretary to the committee which is proposed. The work that will devolve upon him will be laborious, and though it will, no doubt, to some extent, bring its own reward, the committee feel that such a task should not be undertaken gratuitously.

The committee also believe that it may be desirable to make some remuneration to those persons who shall be found to have given the time and attention which is requisite to make careful observations and record them well; and they think it will be agreed that a portion of the funds of the Association can scarcely be better employed than in inducing the individual members of the Association to contribute their share to the advancement of medical science by a careful and systematic observation and record of the facts which come under their notice.

The committee propose the appointment annually of a committee of seven, to be known as the Combined Observation Committee, to arrange, superintend, and direct the work; to meet when and where they please and report annually; the appointment of a paid secretary who shall attend such branch meetings

of the Association as may be desirable for explaining the nature and objects of the investigations and to interest and direct the members of the Association in the work; the appointment by the branches of registrars who may assist in the work, and that such registrars, shall, together with the "Combined Observation Committee," form a "General Committee" to determine from time to time the subjects for investigation, and the manner in which such investigation shall be conducted.

The following have been suggested as likely to form suitable subjects for combined observation. They are merely mentioned to indicate the kind of work which is contemplated. It would rest with the general committee to consider their suitability, or to select others.

(1.) Records of the medical life-history of patients, including the sequelæ of various diseases. (2.) Records of the relationship of certain specified diseases — as, cancer, tubercle, syphilitic degeneration, osteoarthritis, chorea, etc., to any other diseases. (3.) Observations respecting epidemic diseases in given districts. (4.) The incubation period of contagious diseases; and the duration of contagion. (5.) The origin of contagious diseases. (6.) The collection of evidence as to the effects of certain remedies. (7.) The geographical distribution of diseases. (8.) Anthropometrical observations, especially in relation to disease. (9.) The hereditary influence of race, climate, occupation, food, etc., in the production of diathesis or of tendencies to certain diseases.

These quotations give an idea of the work as far as it has been perfected.

The subject is one of great interest and may be made of great importance. The good to be obtained cannot be foreseen. Much may be accomplished in able hands. In idle or otherwise occupied hands the good intentions with which the work is commenced would probably simply serve to extend the plutonic pavement. What will be accomplished the future alone can determine, but the inception and the attempt does great credit to the Association, and is simply a continuation of its good works. We speak of it here not merely because it is interesting in itself but because it shows that there is something for societies to do beside listen to papers, elect officers, and eat dinners, however interesting such exercises may be and however well done.

**THE INTERNATIONAL COMMITTEE OF THE RED CROSS SOCIETY OF GENEVA.**

THE International Committee of the Red Cross Society of Geneva has just issued a circular and an announcement which should attract general attention. In the pursuit of the excellent objects of the Society, and profiting by the present happy state of peace, which liberates its funds and energies to prepare for wars which the future must inevitably bring, the committee offer prizes for the best original papers upon three subjects bearing upon methods of *improvising*

the means of succor for the sick and wounded of armies.

The first subject is The Improvisation of Means of Treatment; the second, Improvisation of Means of Transport; the third, Improvisation of an Ambulance or of a Campaign Hospital.

Although recognizing that the three subjects proposed for competition are but parts of one general subject, namely, The Improvisation of Means of Succor, the committee has thought it best to offer separate prizes rather than one general prize, feeling that in this way better and more varied contributions would result; that individuals, owing to special experience, might feel themselves competent to contribute suggestions of value and originality to one branch of the subject who would hesitate to discuss the whole. At the same time the committee distinctly states that nothing in the terms of their announcement is to be interpreted as preventing or discouraging the same individual from competing for and receiving the prizes offered on all three subjects. The richness of the material and the multiplicity of the requisite investigations offered additional reasons for the adoption of the form given to these prizes by the committee of the Society. In any case the successful monographs can eventually, at the option of the Society, be published together under the same covers, thus forming a single volume, and offering many of the advantages of one consecutive treatise.

Under the first head the committee mentions the following as some of the topics which naturally suggest themselves for consideration: the use of hæmostatics, of apparatus for fractures, of refrigerants, the most practical means of applying Listerism in an efficacious manner on the field of battle, etc., etc. It would also be proper for the writer on this subject to review the furniture, and the utensils in common use, the articles of linen and of apparel, the products of the soil, etc., all of which, though varying with the climate, the soil, and the surroundings, still offer many resources, and to suggest the advantages which the relieving party may derive from them according to the seat of a wound or the nature of a disease.

Under the second head, the Improvisation of Means of Transportation, the following topics are suggested: the best means of transporting the wounded or sick when neither litters, nor carriages, nor any kind of vehicle have been previously provided for the purpose, and the adaptation of railway carriages to this end when not previously prepared.

Under the third head, The Improvisation of an Ambulance or Provisional Hospital in the neighborhood of an army, are naturally to be considered the choice of situation, the appropriation or construction of a building or shelter, the organization of its service, its management, its furniture, and supplies.

The committee, while wishing to leave as much liberty as possible to competitors to treat the allotted subjects as they individually understand them, impose some conditions, as follows: 1. (a) the writers must confine themselves to the improvisation, strictly interpreted, of means of succor, and not wander off to the

previous preparation of such; (b) they must describe carefully the methods they propose (whether original or taken from others), and furnish, when possible, good drawings sufficiently intelligible to allow of the construction of the apparatus they represent; these papers should not be mere manuals, but scientific treatises from which the elements for manuals may be subsequently taken, if thought desirable; (c) the procedures proposed should, as far as possible, have been put to the test of personal trials, and not simply consist of theoretical ideas which are so apt to break down later in practical experience; it is not demanded that these trials should have been made in actual warfare, but only that they should be conclusive and described with accuracy.

(2.) The competitors' papers must be in manuscript and unpublished; they may be written in English, French, or German; they must be sent to the President of the International Committee of the Red Cross Society, No. 8 Rue de l'Athénée, Geneva, Switzerland, before April 1, 1883; each paper must be stamped with a motto, which shall be sent in a sealed envelope with the name and address of the author.

(3.) The examination of the papers shall be entrusted to a jury chosen by the International Committee, the members of which shall be selected from different nationalities.

(4.) The jury may award, in each of the three given subjects, a single first prize of two thousand francs, and supplementary prizes to the amount of five hundred francs; the right, however, is expressly reserved for the jury of not declaring any first prizes if, in its judgment, they have not been earned; in which case the jury may propose to the committee the augmentation of the supplementary prizes. The jury is to render its decisions with the reasons therefor to the international committee, which will publish them in its Bulletin.

(5.) Those monographs which gain the first prizes of two thousand francs shall become the property of the committee, which alone will possess the right of publication, whether in their original language, or in translations—a right, however, the committee agrees to waive unless it should, within a year after the announcement of the awards, have notified the writers of an early intention to publish.

(6.) Should the report of the jury select certain portions of the unsuccessful papers as worthy of honorable mention, the committee would publish such, with the consent of the authors, and over their names, after the successful papers.

The amount of these prizes is sufficiently considerable to be a temptation, the conditions are liberal, the time is long enough, and the subjects proposed for competition are both interesting and important. In addition, the successful competitors will be proclaimed to a very wide audience. The inducements, therefore, to compete are far from insignificant. It must be that our War of the Rebellion and life on the Western plains, united with the proverbial American resources in emergencies and readiness of invention, have offered ideas and experiences to officers in our

army or to men now in civil life which could be properly and profitably put to honorable use in the direction indicated by the announcement of the International Committee of the Red Cross.

### MEDICAL NOTES.

— We learn from a private letter that there has been nothing new in the way of operations in Vienna lately. The "Magen resection" is still the all-important topic, but its success seems very doubtful, as yet, although Billroth does every one that comes along. Only three of all that have been done by anybody are alive; Wölfler, Billroth's assistant, in attempting one, after opening the abdomen found the operation impossible owing to adhesions and great infiltration of the peritonæum, so he cut a hole in the stomach near the commencement of the greater curvature, fished up a portion of the small intestine, cut a hole in that also, and sewed the two together. The patient lived over two months and died of "phthisical symptoms." Billroth thinks that the best operation yet devised when from any cause the pylorus becomes occluded.

— A company, entitled the Zander Medico-Gymnastic Company (Limited), has been established for the purpose of supplying London with the mechanical appliances of Dr. Zander, as well as with skilled advice in the use of them. The institution is at 7 Soho Square, and already fifty or sixty machines are erected of the greatest ingenuity and niceness. Some of them are worked by an engine, others are worked by the patient himself. Dr. Zander's system of treating various diseases, internal and external, partly or chiefly by the use of machines applicable to various parts of the body, and producing various movements or sensations by which circulation and muscular action are both stimulated, has been practised in Stockholm for sixteen years, and, according to varied testimony, with much success. It is a gymnastic system, in which, as in so many other directions, human work is replaced by the work of a machine.

— In an editorial suggested by the burning of the Vienna Theatre, the *London Lancet* suggests what it considers the proper course to be adopted in London for the prevention of such a catastrophe. Its plan is to place the safe custody of our places of amusements in the hands of the chief of the local fire brigade, free from official interference, and to charge him with the duty of making and enforcing necessary regulations; to let him arrange the modes of escape, and place experienced and practiced members of his force on personal duty at the theatres; and to confide the whole management of the theatres and their audiences to competent and practical hands, at the same time giving the person charged with this important public duty the amplest powers. There need be no paltry economy in this matter as regards theatres; the full cost of all necessary or expedient provisions, including the maintenance of an efficient corps of real firemen — working members of the brigade, and therefore not

only in training but in constant practice — might be charged as a tax or rate on places of public assembly, duly apportioned to their size.

### PHARMACEUTICAL NOTE.

The dialysates of alkaloidal drugs as new pharmaceutical preparations are gaining favor. They are prepared from the crude drug by the process of dialysis, whereby the definite, proximate principles are almost entirely separated from most of the other inert and interfering substances. Another advantage connected with them is this, that they are maintained at a uniform strength, based upon the ascertained average alkaloidal strength of good specimens of the drug. This uniformity is increased by a system of assays, one of which is used to check the other. The list included only such drugs as contain definite active principles recognizable and perceptible by reagents. Nearly all of them have been carefully tried in Bellevue Hospital, New York city, and up to the present time have been found to produce the peculiar effects of the different drugs in a more rapid manner than has been the case when administered in most of the other forms.

### Disseclamp.

#### THE MEANING OF KEITH'S ABANDONMENT OF LISTERISM.

MR. EBBRON. — At the late International Medical Congress in London Mr. Keith formally pronounced against the use of anti-septic precautions in abdominal surgery. He admitted having had *eighty successive recoveries* under the Lister method, and said if he stopped there "the showing would have been wonderful, but," he added, "out of the next twenty-five cases I lost five, three from carbolic acid poisoning, one from renal hemorrhage, one from septicæmia." In this matter, however, there seems to be a wheel within a wheel. There was more which Keith did not add. In the first place he did not say that whenever he used the spray he experienced an attack of hæmaturia, and again, and more important, he did not say that in these twenty-five cases he used a solution of carbolic acid which was *one tenth stronger* than that prescribed not only by Lister but by the commonly adopted proportions of the spray. This in itself must have had an absolute effect in the fatal cases, three of which were poisoned by the acid, another dying from renal hemorrhage. Mr. Keith must have very strongly influenced the surgeons who listened to his address, but if he had included the facts I have mentioned, and which were communicated to me by an English ovariotomist who *does* believe in the spray, it is not unlikely that his audience would have mingled a few grains of salt with the impression Mr. Keith's statements may have created. At any rate it would have been fairer in him if he had mentioned these data, the truth of which seems unimpeachable.

When a surgeon of Keith's reputation announces before such a body of men as formed his audience at the Congress his complete loss of faith in a procedure which has created a revolution in surgery and has won so many distinguished adherents, he should not only give *all* his reasons, but if, as Mr. Keith had done, he

had taken the liberty to increase the strength of the carbolic solution, precisely in those cases of which five were fatal, this more than all else should be stated. This was the only fair and honorable course open to Mr. Keith. Not having taken it he has injured and lessened the force of all he did say, and his other reasons for abandoning the spray fall to the ground. That he allowed himself to commit this error is somewhat surprising, for a man whose experience and fame have given him great influence cannot too carefully measure the weight of his denunciation of a method so valuable as to have secured the faith of the leading surgeons of Christendom.

Mr. Keith's position in reference to the spray suggests that which a naval engineer would occupy if he condemned the use of steam because in his hands it has destroyed several vessels, but neglects to mention the insignificant fact that his steam pressure was ten per cent. higher than, according to all approved tests, any boiler can safely bear.

It must be admitted, moreover, that on this occasion Lister not only did not stand to his guns, but apparently had but little ammunition for them, much to the surprise of his adherents, who looked for broad statements, comparative statistics, and a reasonable refutation of Keith's arguments. This may partly be explained by a remark of the English ovariotomist to whom I have referred, namely, "Lister is not up in abdominal surgery. He has had but little experience in it." However this may be, Mr. Lister in this instance seems to have lost that easy flow of language with which for three long hours he entertained the surgical section of the American Medical Congress in 1876. In his reply to Mr. Keith he seemed embarrassed. He had no arguments. He went so far as to say he had never admitted that abdominal surgery was the touchstone of Listerism. On the other hand he cited two recent cases of ovariotomy in which the results were excellent, and in reference to them said, "I could hardly believe I should have got such results without the antiseptic plan. I did not before I used it." Again he said he was not sure that before the next Congress he should not have abandoned the spray altogether.

Hitherto Lister has shown himself such a valiant fighter in behalf of Listerism, he has so unfalteringly evinced the courage of his opinions, and has so persistently clung to the antiseptic treatment of wounds, that this sudden weakening on his part gives rise to wonder. His admissions were too ready, were given under the pressure of too great mental confusion. As has been shown, he not only announced that he himself might abandon the spray, but he did not even suggest a substitute. He made no mention of any other form of antiseptic treatment. He gave next to no reasons for his new and surprising position. It seems but too evident that on this occasion there was some grain of sand which threw his mental machinery out of gear. How else account for the inconsistent tone of his remarks? How else explain the embarrassment of a man who stood under the very vine and fig-tree of his own domain, and upon which until now he has shown such vigor of faith in himself and in his system?

Thus the matter became serious, for Lister's inefficiency of argument, combined with Keith's denunciations, were enough to shake the faith of the surgical world in Listerism. But when one considers that in his account of his last twenty-five cases Keith withheld information which probably would have imperiled

all he did say, and that Lister has not had a large experience in abdominal surgery, and therefore forebore to make the strong statements which he might have applied to the use of the spray in amputation, for instance, the case truly seems to take on another aspect.

The question now arises as to what effect all this may have exerted upon the operation of ovariotomy? The pros and cons of the use of the spray are of course no longer in the keeping of Lister, for hundreds of surgeons have tried, proved, and adopted it. Satisfied of its usefulness, convinced that ovariotomy can be more safely and successfully performed under its influence, they will not incline to abandon it in spite of Keith's defection and Lister's failure to support Listerism, unless some substitute of greater certainty be offered.

In his report of twenty-five cases of ovariotomy, in which the two deaths could probably be explained by the fact that in these instances the operation was performed during a season of intense heat, Dr. John Homans, of Boston, insists that he owed his success to the use of Listerism. With this assertion in view, one would hardly expect him to abandon the spray because Keith has done so, and Dr. Homans has rendered this feeling a certainty by the following reply to a question bearing upon the matter: "I attribute whatever measure of success I obtain in ovariotomy to Listerism and increased experience in operating, *i. e.*, familiarity with different appearances and conditions, and more or less facility in dealing with them. When Mr. Keith has had eighty successive recoveries without the spray, I shall be willing to think of giving it up; at present I am unwilling to do so." That this will be the judgment of many another ovariotomist and surgeon, both at home and abroad, there is small reason to doubt, especially when the whole truth of Keith's new departure becomes known.

The general feeling among medical men probably is that Lister is in duty bound to put on record a better and clearer statement of the opinions he expressed at the Congress, — opinions which were so conflicting and inconsistent as to leave the mind in confusion as to what he really did mean.

Desiring to free myself from any possible charge of injustice to Mr. Keith, I may say that the two impressive points which he left unmentioned were voluntarily communicated to me in a conversation on the merits of the Keith-Lister discussion, my informant being worthy of implicit confidence. If I felt any doubt of the truth of these statements I should hesitate to use them in this way. There being no apparent reason for such feeling, I give them to you with the criticisms they very naturally suggest, hoping they may result in a free expression of opinion touching the whole matter (one of serious import) in England as well as in this country.

H. O.

#### LETTER FROM LEIPZIG.

AGREEABLE IRON PREPARATIONS USED IN GERMANY.

FERRUM OXYDATUM SACCHARATUM SOLUBLE; TINCTURA FERRI POMATA; PYROPHOSPHOSAURES EISEN.

MR. EDITOR, — It is unfortunate that among the needlessly multiplied and unsatisfactory forms of iron in American pharmacy, these really valuable preparations, which are in general use and highest esteem in

Germany, have never been introduced, or, if introduced, have escaped the attention they deserve.

Whether their introduction has been attempted I do not know. It would be surprising if it had not, but if it has, the negative result, it seems to me, can only be due to failure in preparation, for these forms of iron are far more satisfactory in every way than those in common use with us.

If put before the profession they could not fail to attract attention, especially the first preparation of which I shall speak, as being, while equally efficacious, far less injurious, and infinitely more agreeable, than any of the common American preparations, some of which injure teeth, some the digestion, and some both, and few of which are agreeable to the patients.

In consideration of these facts I venture to give a detailed account of the preparation of the first two, with the precautions found in Hager's Commentary, and those given me by Herr Blaser, an experienced pharmacist in Leipzig.

*Ferrum Oxydatum Saccharatum Solubile*, or "*Eisen Zucker*," is an elegant preparation, and is the form most commonly used in chlorosis and for children. It is a sweet-tasting, light-brown powder, easily soluble in water, but may be taken in its natural form. It does not discolor the teeth, and on account of its rapid absorption it may be taken for any length of time without affecting the digestion, even in cases where iron is not always well borne, as in fever, dyspepsia, and cases of gastric disturbance. It may be also taken with substances, as milk, having an alkaline reaction without altering their taste.

The method of preparation is as follows:—

"Take *liquoris ferri sesquichlorati* (G. Ph.), and simple syrup, each twenty parts (20). Add forty (40) parts *liquoris natri caustici* gradually, with stirring, and set aside twenty-four hours. Pour the clear fluid into three hundred (300) parts of boiling distilled water, shake and set aside to settle. Decant, and add distilled water to the precipitate. Collect in a filter and wash with distilled water till the water is colorless, and still shows a rather strong alkaline reaction. The precipitate, being freed by dropping of most of the water, is mixed in a porcelain vessel with ninety (90) parts of best powdered sugar and dried at 100° C. Then add powdered sugar till one hundred (100) parts are filled out. Pulverize and keep in a well closed vessel.

"The result should be a brownish-red, sweet, and pleasant-tasting powder, completely soluble in five parts of water, making a brownish-red, weakly alkaline fluid. One hundred parts of the powder contain three parts of metallic iron."

The precautions are as follows: As an excess of the soda helps the formation of glucic acid, which gives the preparation a darker color, it is better to add, instead of forty parts, only enough to carry the precipitate again into solution, that is, perhaps thirty parts. On adding to water, let boil a few minutes to hasten the precipitation, otherwise a day or two may be required, especially if the amount of soda given in the Pharmacopœia is used, for this retards the precipitation.

It is also suggested to add, instead of three hundred parts of hot water, five hundred to six hundred parts. The water is in both cases better hot, to facilitate the separation.

Herr Blaser tells me that the preparation is so difficult, that half a dozen failures are not to be wondered

at. He insists on the following conditions. The mixture of soda and iron must be kept on the ice, the soda being kept on the ice and only added in small quantities with pauses to allow the mixture to cool, as the heat produced by chemical action is fatal to the success of the precipitation. In no case should a temperature of 50° C. be reached. The dose is 0.2, 0.5, 1.0 grammes two to four times a day, in powders, pills, or pastiles. Herr Blaser dispenses chocolate lozenges, each containing 0.1 of the *ferrum oxydatum solubile*, which are very inviting.

For mixtures may be used the *symplicis ferri oxydati solubilis*, which is prepared as follows:—

The mass, which in the preparation of the *eisen zucker* is formed by mixing the still moist precipitate with sugar, is digested in a water bath for two hours, the water being replaced as it evaporates. After cooling, white syrup is added to three hundred parts.

The result is a clear, dark-red, sweet-tasting fluid. Mixed with five parts of water a precipitate is formed. One hundred parts of the syrup contain one part of iron. If kept long in the air the alkali is neutralized by the carbonic acid of the air, and the iron hydrate, held in suspension in the syrup, is precipitated. Such a cloudy syrup can be generally made clear again by adding a few drops of sodic hydrate and boiling.

The dose is 3-10 grammes two to four times a day. The syrup cannot be used with tinctures or chemical medicaments.

*Tinctura Ferri Pomati*.—This contains less iron than the *eisen zucker*, and being also an agreeable preparation is much given to children. It is a dark-colored, pleasant-tasting fluid of which the dose is for adults fifteen to twenty drops, for children five drops in water. The formulae in the Pharmacopœia is:—

*ÿ Extracti ferri pomati* . . . . . partem unam (1)  
*Aque cinnamoni spirituose* . . . . . partes novas (9)

The extract is prepared as follows: Fifty (50) parts sour apples are reduced to a pulp, mixed with finely-cut straw, and pressed. After being allowed to settle, the supernatant fluid is filtered, and then heated in a water bath (*Dampf Bad*) with one (1) part powdered iron, or enough to be dissolved with a little residue. Water to forty-eight (48) parts is added to the cooled fluid, and after filtration the mass is brought to the consistency of a thick extract.

The extract is of a greenish-black color, and dissolves clear in water. In one hundred parts it contains seven to eight parts iron according to the amount of acid in the apples themselves and that formed by their fermentation. It is better to let the apple juice ferment for two days so that it may be richer in acid, and hence in iron. The apples must be very sour. Hager says it is immaterial whether they are ripe or unripe as long as they are allowed to ferment, but Herr Blaser tells me they should be unripe, and that the best apples for the purpose are small sour ones which are unfit to eat.

The apples are reduced to a pulp in an iron mortar, mixed with the straw and pressed. The juice is placed in a warm situation (in a porcelain or stone vessel) and allowed to ferment for two days. To the fermented juice is added the iron, a silver spoon hastening its solution. The solution, with the aid of moderate warmth and with frequent stirring, should not take more than two or three days, and after that time it will be difficult to get more into solution, as the acid in the apples rarely reaches more than one and one half per

cent. The water as it evaporates is not to be replaced.

A favorite preparation of iron for elegant practice in Germany is the *pyrophosphores eisen*, which is soda water containing the pyrophosphate of iron in clear solution. Unfortunately the method of the preparation is kept a secret by the firm who discovered and who furnish it. This is bought by the bottle or case and taken at dinner.

Another form of iron much given, in Leipzig certainly, and I think in Germany generally, is one which has been introduced in America, though I am sure it is not so extensively used there. This is the *syrupus ferri pyrophosphorici cum ammonio citrico*. It was formerly given in Leipzig under the name of "Syrupus Napoleonis," this being said to have been the only form of iron Napoleon III. would take. This name was given up about ten years ago, and it appears now under its more cumbersome title.

This syrup, which was adopted by the German Pharmacopoeia in 1857, and the French in 1866, has, as far I can judge, hardly received in America the attention it deserves, for it is a very pleasant preparation to take, though not to be compared to the "eisen zucker," which if properly made cannot fail to please the palate of the most fastidious. This I can affirm from personal observation, having seen Americans, who at first demurred at taking iron at all, from having experienced its unpleasant effects at home, taking this preparation regularly with pleasure and apparent benefit, and without the least detriment to teeth, appetite, or digestion. This experience, together with the remarks of American physicians I have met in Germany, leads me to write this article to call the attention of the profession to these extremely valuable preparations.

GEORGE L. WALTON, M. D.

#### IMPORTATION OF SMALL-POX FROM CANADA.

THE following correspondence, relative to the spread of small-pox, from Canada, transmitted by the honorable Secretary of State, is published for general information in the *Bulletin* of the National Board of Health:—

DEPARTMENT OF STATE, WASHINGTON, {  
May 26, 1881. }

THE RT. HON. SIR EDWARD THORNTON, K. C. B.,  
etc., etc.

Sir,—I have the honor to bring to the attention of the Government of the Dominion of Canada, through you, a circumstance which is causing apprehension in the manufacturing districts of Massachusetts, whither Canadian subjects resort at this season to obtain employment in the factories for a limited period.

I am informed by the governor of the State of Massachusetts that small-pox appeared in the town of Adams, in that State, about seven weeks ago, in the person of a young French Canadian woman, since which time forty-nine persons have contracted the disease, of whom nine have died and others are not expected to recover. All those affected are reported to be, without exception, from the Dominion of Canada. Twenty-four of them have become a charge upon the charities of the State.

Within the past two years similar outbreaks of small-pox have occurred in Fall River, Salem, Holyoke, and Williamsburg, the sufferers being almost exclusively persons recently arrived from Canada.

The comparative immunity of residents of Massachusetts from the ravages of small-pox is largely due to the rigid enforcement of the vaccination laws of the State; for example, no child is admitted to the public schools there without complete evidence of previous vaccination. Sanitary laws of like tendency are believed to exist in Canada, but, from the recent occurrences, the conclusion is unavoidable that their enforcement is neglected, and that the subjects of the Dominion coming to this country to seek temporary employment are in a dangerously unprotected state.

The subject cannot but be one of grave interest to the authorities of the Dominion, inasmuch as the Canadian communities must be at least as much exposed to the calamitous outbreak of small-pox as are the American communities visited by Canadian immigrants, and it behooves them to see that the Dominion laws are adequate for domestic protection, and strictly enforced.

It may become necessary for this government to consider the propriety of adopting measures of self-defense, such as the compulsory examination of Canadian immigrants at the frontier, or some equally inconvenient and restrictive step. Meanwhile, it seems proper that I should make the subject known, through you, and ask earnest attention thereto on the part of the Canadian Government.

I have the honor to be, etc., JAMES G. BLAINE.

WASHINGTON, October 29, 1881.

HON. JAMES G. BLAINE, etc., etc.

Sir,—Referring to your note of the 26th of May last, complaining of the prevalence of small-pox amongst Canadians emigrating to the United States, I have the honor to inform you that Sir Edward Thornton brought your note to the notice of His Excellency the Governor-General of Canada, inviting at the same time the attention of the Dominion Government to the matter. His excellency has now forwarded to me a copy of a report from the honorable the Privy Council of Canada, replying to the observations made by you, from which it appears that although small-pox does sometimes make its appearance in Canada as in other countries, and notably in parts of Europe at the present moment, still every precautionary measure possible is taken against the spread of the disease. Efforts are made to cause vaccination to be generally practiced in Canada, and even among the Indian population in the territories vaccinators are occasionally sent by the federal and local governments to enforce the practice in as far as possible.

The committee point out that small-pox is not unfrequently brought to Canada from the United Kingdom, from parts of the continent of Europe, and from the United States, notwithstanding the vaccination laws and regulations of those countries, and complaints even this year have occurred in the province of Quebec of small-pox brought there from the United States.

The committee, after due consideration of a report furnished to them by the minister of agriculture, is of opinion that the Dominion Government will be unable to do anything in addition to the present precautionary measures taken to prevent the recurrence of cases of small-pox being sometimes conveyed to the United States and *vice versa*.

I have the honor to be, with the highest consideration, sir, Your obedient servant,

VICTOR DRUMMOND.

## CONDENSED MILK.

DR. VOCKER, in the *Dairy Association's Journal*, says that not infrequently condensed milk is represented to be nothing more or less than milk evaporated, at a low temperature, to a certain degree, with the addition of white sugar. If whole milk rich in cream is evaporated to a small bulk, even with the greatest care, the resulting condensed milk, when mixed with water,

throws up oily globules, tastes somewhat rancid, and is not as good and sweet as condensed milk produced from partially skimmed milk. Really good condensed milk, as a matter of fact, is always made from skimmed milk, or from milk unusually poor in cream. It is not therefore a perfect substitute for new milk either chemically or physically; at the best, most kinds of good condensed milk are milk syrup, consisting of concentrated skimmed milk and sugar.

## REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 31, 1881.

| Cities.                             | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |                      |

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE. OCTOBER 1, 1881, TO DECEMBER 31, 1881.

HEBERSMITH, ERNEST, surgeon. Relieved from duty at San Francisco Cal., and placed on waiting orders. November 7, 1881. Relieved from waiting orders. November 28, 1881.

VANSANT, JOHN, surgeon. Granted fourteen days' leave of absence. October 18, 1881. To proceed to San Francisco, Cal., and assume charge of the service at that port. November 8, 1881.

MILLER, T. W., surgeon. Granted leave of absence for seven days. October 6, 1881.

PERVANCE, GEORGE, surgeon. To proceed to Boston, Mass., and assume charge of the service at that port. November 8, 1881.

AUSTIN, H. W., surgeon. To proceed to Galveston, Indianola, Corpus Christi, and Brownsville, Texas, as inspector. October 17, 1881.

FISHLIE, J. C., passed assistant surgeon. To proceed to Yorktown, Va., as inspector. October 14, 1881. Detailed as member of Board for the examination of keepers and crews of the Life Saving Service, Third District. November 18, 1881.

GOLDSBOROUGH, C. B., passed assistant surgeon. Detailed as member of Board for the examination of keepers and crews of the Life Saving Service, Fifth and Sixth Districts. November 2, 1881.

O'CONNOR, F. J., assistant surgeon. Granted leave of absence for fifteen days, on account of sickness. December 23, 1881.

GRITTERS, JOHN, assistant surgeon. Granted leave of absence for ten days. December 5, 1881.

BLESSON, J. A., assistant surgeon. Granted leave of absence for twenty-one days. December 7 and 21, 1881.

BANKS, C. E., assistant surgeon. To assume temporary charge of the service at San Francisco, Cal., until the arrival of Surgeon Vansant. November 7, 1881.

CARMICHAEL, D. A., assistant surgeon. To proceed to Baltimore, Md., for temporary duty. November 2, 1881. To rejoin his station (New York), and thence proceed to Pittsburgh, Pa., and assume charge of the service at that port. November 18, 1881.

BLUNETT, P. H., assistant surgeon. To proceed to Boston, Mass., for temporary duty. October 21, 1881.

PECKHAM, C. T., assistant surgeon. To report for temporary duty to surgeon in charge, Boston, Mass. October 21, 1881. To proceed to Vineyard Haven, Mass., for temporary duty, November 4, 1881. To rejoin his station (Boston), and thence proceed to New York, reporting for duty to surgeon in charge. November 9, 1881.

AMES, R. P. M., assistant surgeon. To proceed to St. Louis, Mo., for temporary duty. October 21, 1881. To proceed to Evansville, Ind., for temporary duty. December 21, 1881.

DEVAN, S. C., assistant surgeon. To proceed to San Francisco, Cal., for temporary duty. October 21, 1881.

FRUHLI, F. M., assistant surgeon. To report for temporary duty to surgeon in charge, New York, N. Y. October 21, 1881.

APPOINTMENTS. The following candidates having passed the examination required by the regulations were appointed as

assistant surgeons by the Secretary of the Treasury, October 20, 1881:—

PHILO H. BENNETT, M. D., of New York,  
CYRUS T. PECKHAM, M. D., of Massachusetts,  
ROBERT P. M. AMES, M. D., of Pennsylvania,  
SPENCER C. DEVAN, M. D., of Missouri, and  
FRANCIS M. URQUHART, M. D., of New York.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 31, 1881, TO JANUARY 6, 1882.

TREMAINE, W. S., captain and assistant surgeon. Now awaiting orders in New York city, to report in person to the commanding general, Department of the East, for assignment to duty. S. O. 2, A. G. O., January 4, 1882.

POWELL, J. L., first lieutenant and assistant surgeon. The seven days' leave of absence granted him in orders 186, Fort Stockton, Texas, is extended fifteen days. S. O. 159, Department of Texas, December 27, 1881.

CARTER, W. F., first lieutenant and assistant surgeon. The seven days' leave granted him by orders 155, C. S., Fort Concho, Texas, extended one month, providing he furnish an acceptable substitute during his absence, without expense to the United States. S. O. 160, Department of Texas, December 29, 1881.

GORGAS, WILLIAM C., first lieutenant and assistant surgeon. The leave of absence granted him by paragraph 5, S. O. 150, headquarters, Department of Texas, December 3, 1881, is extended one month. S. O. 1, Military Division of the Missouri, January 4, 1882.

MADDON, THOMAS J. C., first lieutenant and assistant surgeon. Now awaiting orders in Washington, D. C., to report in person to commanding general, Department of Texas, for assignment to duty. S. O. 2, A. G. O., C. S.

NATIONAL ASSOCIATION FOR THE PROTECTION OF THE INSANE AND THE PREVENTION OF INSANITY.—A meeting of the members of the National Association for the Protection of the Insane, etc., and invited guests, will be held at Municipal Hall, 67 Madison Avenue, New York city, on Friday evening, January 20th, 1882, at eight o'clock p. m. Speakers and topics announced hereafter. A. A. CHEYALLIER, Secretary.

H. B. WILBUR, M. D., President, Syracuse, N. Y.

N. B. A business meeting of the Council of the Association will be held at the above address at four p. m., on the same day. A full attendance is earnestly requested.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting of the Society will be held on Monday evening, January 16, 1882, at eight o'clock. Reader, Dr. McCollom. Subject, The Use of the Obstetric Forceps.

M. H. RICHARDSON, Secretary.

TWO FATAL CASES OF PLEURITIC EFFUSION ;  
WOULD NOT THORACENTESIS HAVE SAVED  
LIFE IN BOTH? GERMAN AND AMERICAN  
THERAPEUTICS IN THE DISEASE.

BY HENRY I. BOWDITCH, M. D.

THE secretary of the section having requested me to prepare a paper for this evening I thought that I could not aid him better than by giving a *résumé* of two fatal cases of acute pleuritic effusion, in which I believe that thoracentesis would probably have saved life. One of these cases occurred in Boston about twenty-five years since, and to it I was called in consultation. The other happened in 1873, under the care of an eminent German teacher in a German capital. Both cases have been painfully instructive to me. If I seem to criticise too severely the treatment pursued, please remember that I think life was sacrificed by most grave errors of commission in one, and of omission in both.

I shall relate in some detail the German case first.

It was that of an American student of medicine. His family tendencies were consumptive, his mother and uncle having died of phthisis. He had been liable to severe colds accompanied by cough, but I cannot learn of any severe pulmonary attack. The autopsy, however, proved that, at some antecedent period, he must have had an attack of pleurisy, as proved by adhesions of the pleuræ. He had been able to walk in Switzerland with able-bodied young men without discomfort, and all<sup>1</sup> my informants assure me that he had no settled cough or other symptom sufficient to prevent him from attending at the medical class until within a week of his death. There is no doubt, however, that, owing to certain domestic afflictions (loss of a father, etc.) his mind had been much disturbed, for a few months before his last illness, and one, in daily intercourse with him, remarked that he did not seem quite so energetic as before. He was tired more easily, and small incidents seemed to annoy him, and at times he was worn and exhausted. He was daily at his work, when the following incidents occurred, which may be arranged in three tolerably distinct periods:—

*First Period.* It lasted about nine days. It seemed to be simply a severe naso-pharyngeal catarrh—and no serious symptom was noticed.

*Second Period.* This extended from the ninth to the fourteenth day. He became very insidiously and gradually more ill—without, however, any marked symptom, save a gradually increasing dyspnoea. This symptom annoyed him and was inexplicable at first—although, before any medical treatment was instituted, the patient himself recognized, by percussion, that something caused dullness on percussion of the lower part of the left breast and side. But he had no cough, nor sputa nor pain in the side. As one friend described him, he still “with his usual pluck and determination continued going to his lectures,” and this, too, when, according to another, he had so much dyspnoea that he was compelled to stop at the top of one staircase and rest, before going up the next flight. There was increasing lassitude. His pulse also began

to rise, and the temperature between the ninth and fourteenth day rose from 102.2° F. to 104.8° F.—the mean being 103.8° F. The appetite was a little lessened; the bowels were well. He was evidently gradually growing more ill, but, according to one correspondent, a day or two elapsed after he had recognized the dullness above alluded to, before the patient would consent to summon a physician. At or about this time the following physical signs were found by one of my informants: “Dullness of the lower part of the left side of thorax from a point an inch below the nipple, in a horizontal line around the chest. The respiration was bronchial in the region of flatness, and ‘rough’ over the whole of the left lung. Change of position did not, *materially*, change the sound. The heart was dislocated toward the right; and its apex was felt in the middle of the sternum more strongly than elsewhere. Only one occasional râle was heard over the whole of the left lung. At the back, near the spine, and on a level with the angle of the scapula, a slight friction sound was heard in a space of two by one inches.”

“On the next day, fifteenth from the outset of the first period, the dullness of the chest arose at least one inch, and the dyspnoea became greater.” Yet the student still was about at his work and no proper medical treatment had been commenced. But the friends, then becoming alarmed, persuaded him that an eminent German clinical teacher and physician must be called in, and by their request that practitioner consented to take full charge of the case. His diagnosis was “acute pleurisy,” with effusion. His treatment was followed until death took place, but it soon became very distressing to three of my informants who were daily cognizant of it. None of them felt at liberty to suggest a variation, although one, subsequently, alluded to thoracentesis. But he was summarily checked by the remark that it was “too early to think of that operation.”

This treatment was as follows, as I gather from the notes taken at the time or from conversations I have held with my informant. It marks the—

*Third Period.* Commencing with the treatment, it lasted till death took place, in three or four days.

The patient was immediately ordered to keep his bed; he was not to read or talk or even listen to conversation. In other words, absolute quiet and rest were enjoined.

His diet was to be milk, purée of potato (potato soup or mashed potato), apple, plum, or pear sauce, bread rolls. No tea, coffee, or chocolate.

For medical treatment it was ordered that ten cups should be applied to the side, six of which were to be dry, and four were to be scarified. Twelve ounces of blood were thus drawn from the front and back of the left chest. He was to take one of the following powders every two hours.

|                     |             |
|---------------------|-------------|
| ℞ Calomel . . . . . | grs. xij.   |
| Sugar . . . . .     | grs. iii. M |
| Divide in ch. vi.   |             |

The next day (seventeenth from beginning of cor-  
yza) increase of symptoms, and the following was  
ordered:—

|                         |               |
|-------------------------|---------------|
| ℞ Decod. Aithæ. . . . . | ℥iiss.        |
| Sod. Nitrat. . . . .    | 3i + grs. xv. |
| Syrup . . . . .         | ℥ss. M.       |
| ℥ss. every 1½ hours.    |               |

Scannæ electuarii; a heaping teaspoonful before breakfast.

<sup>1</sup> They were three in number. All of them were in close attendance during his last illness and had knowledge of him during several months before that time.

The effect of these remedies are thus given by one of my correspondents:—

"Condition of patient on the day (sixteenth) after cupping, temperature 103° F., pulse 104, respiration 25. Next morning temperature 101° F., pulse 102, respiration 23. Dullness remained unchanged; five stools during the day. On the following day (eighteenth) there was a sudden increase of the effusion, the dullness reaching to within one inch of the clavicles. Treatment continued, with diarrhœa still remaining. Collapse and almost instant death in the afternoon."

One of my informants says that, while making efforts for a dejection, this collapse took place, and ere long death ensued. Another assures me that, at the morning visit of that day, the attending physician expressed himself as wholly satisfied with the condition of the patient; and this notwithstanding the rapid increase of the effusion, and increasing debility of the invalid.

Autopsy, thirty hours after death. The left pleural cavity was found two thirds filled by serum and a jelly-like substance, about one third being serous and two thirds of this jelly-like mass, which was partly fibrinated in an extremely delicate manner. A "few incipient tubercles" were found in the layers of the left parietal pleura; but none, so far as my informant can remember, were found in the pulmonary pleura or in either lung, which seemed healthy. The left lung was very much compressed towards the spine. One informant, aided by the assistant of the pathologist of the school, examined microscopically the heart fibres with reference to their being fatty. No fat was found. After the sudden death rumor had suggested that it was owing, probably, to a fatty degeneration of the heart. The organ was small and looked weak, and, owing to its displacement, the great vessels were so twisted that the circulation in the lungs must have been interfered with.

The death was a surprise to all. Before it actually took place, one of my informants, seeing the necessity for immediate thoracentesis, notwithstanding the previous opposition of the regular attendant, hurried for his tapping instruments, but it was too late. The medical attendant said it was an unusual case; he had never but once met with one similar.

Before making any remarks upon this case, allow me very briefly to bring to your notice the Boston case, which, as I have already stated, happened many years ago, and in which I failed of doing what I now think would be my duty, were a similar case to present itself. The two cases are entirely analogous in one particular, namely, the failure on the part of medical attendants to tap the chest, whereby life might have been saved in both instances, or perchance life restored in one, if an opening in the chest had been made and artificial respiration had been instituted.

About twenty-five years ago, after three or four years of successful use of thoracentesis as a means of relief or cure of pleuritic effusions, by means of Dr. Wynnan's suggestion of an exploring trocar and suction pump (by aspiration, in fact, as the operation is now called), but before it had been cordially received by the profession generally, I was summoned to a case in consultation. I was surprised to be called by one who, I knew, had been one of the ablest of the opponents of the operation. The patient was a little child, who had been acutely suffering some days from orthopnea caused either by an effusion of fluid, filling

the whole of the left chest, or perfect hepatization of the left lung, the practitioner could not decide. Upon my learning that the heart was at the right of the sternum and there was no crepitanous râle, I told him that, undoubtedly, there was a large effusion, and that thoracentesis was called for instantly. We had a long discussion as to the dangers connected with the operation, at all of which I only laughed, and told him that it was one of the simplest and most harmless. He seemed convinced, and it was agreed that we should meet the following morning, prepared to operate. We met at the appointed hour, but the physician, being, as I found, still in doubt about the propriety and safety of the operation, called me into a lower room, before I saw the patient, in order to talk further upon the matter. While thus engaged, a sudden summons from the sick chamber came to us, with the statement that the patient was dying. We, of course, stopped all debate; and ran up stairs, just in time to see the last gasp and the glazing eyes of death. Without doing or saying anything, we waited a minute or two until entirely satisfied that the patient was dead, when we turned and left the room. I have never ceased to look back upon that event with the greatest sorrow, not to say some self-reproach.

And here allow me to ask you a question and at the same time to answer it decidedly. You will see its pertinency to the two cases just related. If any of you should happen to be present at or immediately after death, connected, as these two were, with pleuritic effusions, what ought you forthwith to do? I answer, unhesitatingly, plunge any instrument you may have at hand, whether aspirator, trocar, penknife, or sharp-pointed table knife, which may be found in any house, instantly, into the side of the chest, where you know the fluid is lying that has taken away breath. Let that fluid run out, regardless of all lack of disinfecting spray, or of any carbolized material, deemed so necessary now-a-days. Then, with an assistant to watch and prevent if possible the external air getting into the pleural cavity, while not checking the outward flow of the effused fluid, do you excite artificial respiration by manipulating properly the walls of the thorax and abdomen and by blowing air into the lungs from your own lips. For the moment, lay aside all fear of germs of disease, for it is better to have impure air than no air at all. Of course, other accidents than apnoea may be the cause of the sudden death in these cases. But because we cannot meet all contingencies, is no reason for our not trying to meet one of the most obvious of them.

Let us now return to the European case. I do not remember to have ever met with one more instructive, while so painful in the suggestions it gives rise to. Under the light of our New England experience, such gross errors, as I deem them, of omission and of commission, seem impossible. But we have witnesses in the notes and observations taken at the time by deeply interested observers. The data were given to me separately, and the accounts support each other. Two of the reporters, medical students, recognized the effusion, its latency and amount, before the professor was summoned to treat the case. Both were surprised at the methods pursued by him. One ventured, as above stated, to suggest thoracentesis; but the proposal was summarily dismissed, on the ground that it was "too early" in the disease for the proposition to be entertained. And yet I cannot but hope that no New Eng-

land physician would refuse this simple operation in such a case, and for such a flimsy reason. Then, too, as to the medical treatment, I do not believe that any New England (may I not say American?), well-educated practitioner of medicine would, even nine years ago, have been unwise enough to use, in such a case, calomel in repeated doses and semia, day after day, so that a severe diarrhoea was kept up, and, at the same time, order such a restricted diet as was used in this case.

Moreover, I should certainly hope that no intelligent practitioner here would *have to wait* instead of instantly tapping the thorax, when he should see the fluid *increasing* daily, with rapid prostration of the powers of the patient under such heroic, mediæval practice, and with dyspnoea ever augmenting. A man who, under such a state of things, would *delay operating because of the early period of the disease* would do so at the peril of the patient's life. I hold that *the question of time, the disease has lasted, should never be used as an argument against thoracentesis, in a case of marked and severe dyspnoea*. In this case it will be remembered that dyspnoea was almost the sole symptom, and was somewhat severe, even before the patient would allow that he was ill enough to have a physician called.

The treatment, I think, should have been thoracentesis on the first or the second day after the physician was summoned, and the system of dragging pursued seems to me most fatal in its tendency. I should have advised an alterative and a tonic course internally, and external irritation by means of the ethereal tincture of iodine (3ss. iodine to ʒi. of ether); but not cupping and extraction of blood in such a case. A nutritious, perhaps non-stimulating, diet should be given, and the use of mild soups or broths, or in feeble constitutions even the chewing, and perhaps swallowing, of beefsteak allowed, and, at times, perhaps a little wine or whiskey might be added. If called to a case at an earlier stage of the disease, with little or no pain in the side and no serious dyspnoea, I usually order iodide of potassium three times a day internally and the ethereal solution of iodine above named externally over the affected side, and direct the patient to keep in the house. In most cases of this nature, I find in two or three weeks the effusion yields without operation. If the dyspnoea become severe at *any time* I immediately tap the chest, as the only safe remedy.

I regret to feel that in our case in Boston twenty-five years ago thoracentesis was fatally neglected, and so it was with the case in Germany. Both patients died, when they might have lived had thoracentesis been performed. But I must protest again most heartily at the drastic and heroic mediæval treatment pursued by the German attendant, under which rapidly the strength of the patient sank. Some may urge against my judgment in this case that thoracentesis and a different treatment would probably not have saved life.

It may be said, *first*, that the fact that so large a part of the effusion was gelatinous it would have been difficult if not impossible to remove it. Any fluid, taken from the pleural cavity by thoracentesis, frequently coagulates almost immediately after removal. No one can be sure that the large, jelly-like mass, found in this case, may not have been mere fluid during life. About thirty hours had elapsed before an autopsy was made, and in this period coagulation may

have increased very much. Let us for the moment admit the difficulty, although by no means the impossibility, of drawing from the chest a sufficient quantity of fluid to have saved life. My reply would be that in my experience hitherto in three hundred and sixty-six operations on two hundred and thirty-two patients I have not more than twice failed to get at least *some* little fluid. In one of these cases a large, solid tumor filled one pleural cavity.

Again, I have almost invariably noticed that when even the *smallest quantity* is removed the patient is relieved, the simple acupuncture, as thoracentesis really is, in such a case, seeming to do good and to stimulate nature towards a cure.

Still further, supposing that we are satisfied that our trocar has entered a gelatinous mass, which cannot be drawn out except with difficulty or not at all, I see no objection to reversing the pump, and injecting into the chest warm water, which had been previously boiled and thus made antiseptic, and immediately withdrawing it. This might be cautiously but repeatedly done, and thereby, perchance, we might succeed in getting at any supernatant fluid lying, as in this case, over the jelly-like mass, a portion of which might obstruct our fine trocar in the early part of the operation.

Another objection to the use of thoracentesis in this particular case may be urged the fact, stated by one of my informants who saw the autopsy, that "incipient tubercles" were found in the layers of the pleural cavity of the diseased side, and that the hereditary tendency to consumption being so strong, the patient, though temporarily relieved, would have died of consumption, at last.

In answer it must be remembered that there were "no signs of tubercle in the pulmonary pleura nor in the lungs," and that all the previous history of the acute attack, with the symptoms that occurred after the attack, and the short duration of the whole are against the idea that it was "a tuberculous case," and that "incipient tubercle" was the *cause of the pleuritic attack*. I hold, therefore, that these "incipient tubercles" (whatever that term means) may possibly have been the *consequence of the pleural inflammation rather than its cause*. If this be true, what was to prevent them from wholly disappearing, if the pleuritic trouble had been cured. The word "*tubercle*" has been, for the past half or three quarters of a century, a scare-crow for the profession. Indeed, it is a word not to be spoken lightly of, but, in such a case as this, it seems to me to be worth nothing as against the propriety, nay, the necessity, for thoracentesis, even if it be for nothing but relief to agonizing dyspnoea.

Gentlemen, I have finished with these two cases. As I have brought them together, and have seen what valuable instruction can be drawn from them, they have become more and more interesting to me. But some may ask, Why bring up from the past such scenes of painful interest, showing only the folly or failures of the profession? My only reply is that we often gain much more from our blunders than from our successes. Still further, I have thought that it would be almost wrong for me to keep silence, after hearing, only recently, of the treatment in the German case. Permit me, in conclusion, to present the following train of thought and advice, which I shall give to any patient of my own, who may travel on the continent of Europe. If we believe that the internal treat-

ment followed in the German case, and the total neglect of thoracentesis, by one of the most eminent clinical teachers of his time, be the usual course, likely to be followed by his pupils now spread over Germany. I think the opinion I shall express, and the advice I shall give, proper and just. If, moreover, it be a fact that thoracentesis, as performed upon the European continent, has proved fatal in many instances, whereas I have yet to learn of any such fatality in New England, and, I think, in America, and when I myself have never met with a death, I am persuaded that the operator is in fault in Europe. I believe the operation, if *carefully done*, with due regard to the *first moment* of suffering on the part of the patient (cough, dyspnoea, stricture of chest), and if immediately thereupon the trocar be removed, is as simple and innocuous as venesection or vaccination. Such a remark does not apply to the operation, as performed in Europe.

My advice, therefore, to my patient visiting Europe will be as follows: If you find yourself threatened with pleurisy, send for an American physician, and trust to him rather than to any other under the influence of continental therapeutics. One exception I feel bound to make. If you are in Paris, summon Mons. Dieulafoy, immediately. He does not decline thoracentesis when necessary; and his rules for the operation are perfectly safe.

This may seem gross presumption on my part, nevertheless I shall feel it my duty to give the advice, upon the argument that, at times, much suffering may be prevented and, possibly, some lives may be saved.

#### CASES OF CONTRACTION AT THE HIP-JOINT.<sup>1</sup>

BY E. H. BRADFORD, M. D.

It has been abundantly proved in surgical practice that obstinate flexion of the femur can be corrected by osteotomy, by osteoclasis, by *brisement force*, in certain cases, by tenotomy followed by gradual or immediate straightening.<sup>2</sup>

It is also known that in the early stage of hip disease, before the tissues have become contracted, simple rest in bed will allow the limb to correct itself, or, under an anæsthetic the limb can easily be placed in position.<sup>3</sup>

After the disease has lasted for some time a contraction, which has been aptly termed "adapted shortening," takes place, and under an anæsthetic the limb cannot be replaced by the employment of force alone. In one cadaver on which I had an opportunity of examining a contraction of this sort, perfect correction could not be gained (although no bony union or firm fibrous adhesions were present) even after the skin was torn and some of the muscles divided.

As is well known, the acetabulum becomes widened and the head of the femur absorbed under the reflex muscular pressure which crowds the femur backward and upward, there being no muscle to pull the limb downward. This produces a position of pseudo dislocation, which, with contraction of the adjacent tissues, constitutes the deformity.

In the following cases treatment was attempted without strictly operative intervention:—

CASE I. R. W., six years old, of healthy parentage, and without a history of previous illness. There is no phthisis in the family. The boy met with a slight fall, previous to the attack of hip disease. This was first noticed in the summer of 1880, and for this he was treated by different regular physicians, for a while in the autumn of 1880 was placed for three months under the care of the Italian bone-setter, Regina Dal-Cein; by her his limb was poulticed and pulled by the hand. He is thought by the mother to have improved while under this treatment, the limb which was somewhat flexed becoming less so. A few months later, however, two abscesses formed; these were incised by the family physician, and after discharging for several months the sinuses healed. The limb began, however, to "draw up," and on September 6th the thigh was flexed at a right angle to the axis of the sacrum. There was no swelling or tenderness about the hip. The head of the trochanter was not above the Nélaton line, and any attempt to extend the thigh caused arching of the lumbar spine. The patient suffered no pain, and the limb was but slightly adducted.

With the assistance of Dr. Otis the boy was etherized, and the limb forcibly pulled. Tenotomy was not done. Comparatively little was gained in this way. An extension splint was then applied, the leg being kept elevated from the plane of the bed to an amount nearly equal to the degree of deformity. A folded pillow was placed under the knee, and an extension by weight and pulley (seven pounds) attached to the end of the splint.

The patient was quite restless the night following the operation, and complained of some pain referred to the knee, and slight muscular twitching was noticed if the extension splint was removed, followed by pain referred to knee. This lasted, however, but about twenty-four hours. At the end of three days the limb was within twenty degrees of the axis of the body. At the end of a week the leg had been brought to the line of the axis of the body. He was allowed to get

No. 1.

No. 2.

up and go about with crutches, and elevated shoe applied to the well foot, wearing the extension splint on the affected limb. No swelling of the hip, tenderness, heat, or redness followed, and the boy remained in every way as well as before the stretching.

At the present time, four months later, there is complete absence of any deformity; there is no difference in the length of the limbs; the boy is able to stand on the affected limb, but as a protection against jar or possible recurrence of the deformity is directed to wear an extension splint.

The condition before operation is accurately indicated in the accompanying outline sketch, No. 1, and

<sup>1</sup> Read before the Boston Society for Medical Improvement, January 9, 1882.

<sup>3</sup> Case II., JOURNAL, November 11, 1880, page 467.

in No. 2 the position of the limb after two and three weeks' treatment.

CASE II. R. F., aged seven, patient at the City Hospital; history that of hip disease of one and a half years' duration. At the time of entrance there was no tenderness about the hip, no motion at the hip. The thigh was flexed to nearly a right angle, and slightly adducted.

The same treatment was carried out in this case as in the previous one except that no extension splint was used. A ham splint was bandaged to the limb to prevent flexion of the femur, and a weight and pulley applied. After etherization the limb could not be straightened more than through an arc of forty degrees. Extension was therefore applied with the leg raised to that amount. This was gradually reduced. At the end of a fortnight extension was in the line of the bed on which the child lay. A certain amount of sagging of the bed prevented perfect correction of the deformity, and the child's hips were therefore raised by placing a pillow under the buttocks. This raised the pelvis slightly above the line of the extension.

At the end of eight weeks he was furnished with crutches and an elevated shoe, and wearing the ham splint allowed to walk about. A week later he was allowed to go about on crutches without the ham splint, and no evil results followed the forcible manipulation.

The skin near the anterior superior spinous processes was slightly torn at the time of the straightening, but no inflammation followed.

The correction of the deformity followed in this, as in the previous case, without difficulty. At the time of discharge from the hospital the patient's limbs were nearly parallel, the affected limb being flexed at the femur at an angle of ten degrees with the axis of the sacrum. After discharge from the hospital careful treatment was impossible.

No. 3.

CASE III. J. S., aged three, hip disease of one year's duration. The patient entered the hospital with the femur flexed firmly, nearly at a right angle with the axis of the trunk, and slightly adducted. There was no tenderness at the hip. The child was a delicate one, but was fairly nourished.

Extension by weight and pulley (seven pounds) was applied in nearly the line of the deformity. To accomplish this a cross-bar was fixed over the foot of the bed and several feet above it. A pulley was fastened to this, over which ran the cord for the ordinary weight and pulley extension. A board covered by a pillow was placed beneath the limb, extending from the buttock to the pulley. The knee was bandaged to this, and the limb in this way supported in the line of the deformity. The board and pulley were lowered from day to day as far as was possible without tilting the

pelvis. At the end of three weeks the deformity was so far corrected that the pelvis did not tilt when the limb was placed upon the level of the bed. The skin in the groin gave evidence of a great deal of stretching, and the patient suffered somewhat from nocturnal pain for ten days, but no disturbance of the general condition followed, and the patient is at present undergoing treatment. The amount of deformity and of correction is indicated by the accompanying tracing, No. 3, taken by placing a strip of lead upon the abdomen and anterior surface of the femur.

In these three cases the deformity was of an aggravated type. In two under an anæsthetic but little was gained except after traction. In the third the weight of the limb was utilized in addition to traction as a means of completing the rectification of the deformity. The amount of force which can be used in this way is considerable, as can be easily demonstrated if any one stands or lies with the limb held for a time at a marked angle with the body (the leg being kept extended and not flexed at the knee). The amount varies with the length and size of the limb.

The accompanying case, an aggravated one, of many years' standing, with cicatrices of old sinuses, shows that something may be gained by this means alone.

CASE IV. E. A., a young woman twenty-two years old. The patient first suffered from hip disease when three years old; her trouble was of an aggravated type. Abscesses formed and sinuses continued to discharge for many years.

At the time of commencement of treatment her thigh was flexed at an angle of about 70° with the axis of the sacrum. The arm was somewhat adducted. The trochanter was two inches above the line passing between the anterior superior spine and the tuberosity of the ischium. The cicatrices of two sinuses were present about the hip and no motion was to be detected. The patient used on this limb a shoe raised five inches, and with this, with difficulty, touched the floor with her heel. The deformity was so marked that it did not appear to be at all probable that any benefit could be derived from non-operative treatment, and nothing would have been attempted, if Dr. C. P. Putnam had not felt confident that the conditions could be improved.

The patient was placed in bed and a ham splint applied to prevent flexion of the knee. This was secured by means of adhesive plaster and a silicate bandage. After the patient had become accustomed to this position, she, a few days later, was allowed to go about as freely as she desired, using crutches. No traction or friction was used, and the correction of the deformity was left entirely to the weight of the limb. This power of course only acted while the patient was standing, and necessarily a great deal of the time the limb was without any correcting force.

At the end of four months a removable splint was applied instead of the ham splint, answering the same purpose, namely, prevention of flexion at the knee.

At the end of six months the deformity had been overcome to an extent indicated by the accompanying tracings,<sup>1</sup> No. 4 and No. 5, and the patient is able to touch her heel to the ground with a shoe elevated three inches. She has during the treatment suffered from a slight amount of transitory pain. At the present time she is

<sup>1</sup> These tracings were taken by placing the patient upon a large sheet of stout paper, and with a pencil marking the outline of the body and limb. They were reduced by photography to their present size. No. 4 shows the patient before, No. 5 after treatment.

able to walk about, using one crutch to steady herself, but is able to bear full weight upon the affected limb.

In cases where the deformity has not been of long standing, even of a pronounced type, a light extension applied without regard to the line of deformity is sufficient to gain the result.

CASE V. M. C., aged eight years; hip disease of six months' duration. The patient's limb was flexed at a right angle with the line of the body. The patient had but little pain or tenderness. A light extension by weight and pulley was applied, the patient being fixed in bed, and the limb in two weeks became perfectly straight. Several months later an abscess formed and in a year the patient died with disease of the liver and kidney.

CASE VI. M., patient aged five, hip disease of four months' duration; flexion of the left thigh to  $40^{\circ}$ . The child was confined and fixed in bed, a light extension by weight and pulley applied without regard to the direction of the deformity; in two weeks the limbs were perfectly parallel and no deformity remained. The patient was kept in bed for several months. At the present time, six months later, the child is allowed to walk about, wearing an extension splint.

The following is a case of deformity of hip disease complicated by actual dislocation, as was discovered on etherization:—

CASE VII. C. W., five years old, a patient at the Children's Hospital, was admitted suffering from hip disease of right side of eighteen months' duration, with an acute exacerbation. The limb was extremely tender, was flexed and adducted. The hip was swollen, hot, and tender. The patient was etherized, and in extending the limb in the manipulation for correction of the deformity the head of the femur was felt to slip into the acetabulum. No bony grating was detected. The correction of the deformity was not complete, as some flexion remained. An extension of eight pounds in two weeks' time brought the limb to the normal position. The patient was relieved of pain and improved in general condition. An abscess, however, formed three months later, and shortly afterwards the child was attacked by diphtheria and died.

As is well known, deformities at the hip joint can in many cases be overcome by the method of securing by bandages the patient to a frame which embraces the trunk and extends along the affected limb. The frame at first is bent according to the amount of distortion, but it is gradually straightened and the limb bandaged in the straightened position.

The following case, one of periarticular disease, illustrates this method:—

CASE VIII. Agnes Powers, a child three years old, entered the Children's Hospital with a right angled contraction at the left hip. Tenderness over the sacro-iliac synchondrosis was marked, and the usual symptoms of hip disease being absent a diagnosis of sacro-iliac disease suggested itself. An abscess, however, formed and on incision no diseased bone could be detected, and the incision healed after thorough drainage. The patient was placed upon a wire frame which reached from the axilla to below the left foot, this was bent according to the amount of flexion, but was straightened from day to day. At the end of three weeks the limb was entirely straight.

It would be too much to assume that the correction of a deformity of this sort was the cure of it. As long as any inflammation remains at the hip joint, or as long as from timidity or habit of disuse the patient is accustomed to hold the limb in an unnatural position, a recurrence of the deformity, to a certain degree, may be considered possible or probable.

To prevent this recurrence either the continued use for a longer or shorter time of the measures taken for the correction of the deformity is necessary, or the treatment of the latent disease at the joint, a description of which does not fall within the scope of this paper, the object of which is to indicate that in certain cases of this class of deformity correction can take place without the usually mentioned methods of procedure.

#### PARAPLEGIA (PARAPARESIS) FROM FUNCTIONAL WEAKNESS.<sup>1</sup>

BY S. G. WEBBER, M. D.

I WILL describe three cases which illustrate three varieties of the affection to which I wish to call attention.

M. J. F., widow, aged twenty-six, entered the City Hospital August 27, 1879. Diagnosis endocervicitis. She had a miscarriage eight years before, followed by inflammation of the womb; this seems to have been unimportant, as she soon recovered from it, and was transferred to nervous and renal service September 24th.

The patient had never been strong; had had all the usual diseases of childhood, lung fever two or three times, typhus fever when a child, rheumatic fever nine years ago, and intermittent fever, typhoid fever twice, the last time March, 1878, complicated with spinal meningitis. When thirteen years old she fell on the ice upon her spine; again, at fifteen years of age, fell down a flight of stone steps, striking upon lower part of spine; was laid up by this for three months, having great difficulty in walking and sitting. After the typhoid fever and spinal meningitis in 1878 she was confined to the house till January 1, 1879. She had had pain in her back for a year, pain in right leg, more than in left, for a year; pricking sensations in legs with numbness for a year past; had had a sense of a girdle about waist; some para-esthesia in legs and back, hyper-esthesia of back, the weight of the bed-clothes lying on her back causing pain; micturition rather difficult, sometimes only once in forty-eight hours; vision defective; diplopia; tremor of hands during voluntary action for the past six months.

<sup>1</sup> Read before Boston Society for Medical Improvement, January 9, 1882.

On examination there was found to be tenderness over the whole spine, varying in degree, most marked over coccyx; tenderness over upper part of abdomen, especially over the epigastrium; slight tremor of hands, increased in right hand during voluntary motion, not in the left; no ankle clonus; patella tendon reflex very much increased on the left, somewhat increased on the right; she walked very feebly, and with eyes shut fell; urine was normal, without albumen, no casts.

She left the hospital October 29th.

She was treated in the hospital with iodide of potassium, two and one half to five grains three times a day, and dry cups to the back. After she left the hospital she was rather worse for a while, could not walk, had attacks of severe pain in the back. The cupping was continued daily, with much relief after each cup, until the close of winter, then less frequently. She slowly gained, and March 1, 1880, she had no pain in her back, walked firmly without assistance. In the winter of 1880-81 she was keeping a boarding-house.

Here was a history of long continued ill health, during which the nervous system must have suffered in common with the system in general. Whether she really had spinal meningitis with the typhoid fever or simply severe backache I cannot tell, and not knowing who her physician was at that time, it is not possible to judge from any knowledge of his skill. Muscular weakness after typhoid is not unusual.

When first seen there was very great weakness, and this continued for several weeks. The great tenderness in the back was the chief symptom leading to a diagnosis of functional weakness. Pain in the back in organic lesions of the spinal cord or envelopes is present, as a rule, only in spinal meningitis; the other symptoms of that affection were wanting in this case. It was not difficult to diagnosticate the real nature of the affection.

Helen F. S., aged thirteen, was delicate and weak all her life. When five years old she had scarlet fever, and had not been well since. Catamenia had not appeared. For one or two years she had been growing feeble, and gradually losing power to walk. The most marked loss of power appeared after taking a long walk, whether this was at the beginning of the loss of strength or subsequently is not known, but it was just before an aggravation of her complaint. About five months before entrance she was entirely unable to walk, though she could still make the motions of walking when supported by her father, and he required this exercise daily. There had been no pain or numbness in feet, but sometimes a sensation as if they were asleep. There had been no spasm nor twitching of legs, no swelling of feet. There was pain in back, but not enough to disturb sleep, and sometimes she had headache, eyes also ached at times.

On examination it was found that she could move her limbs, but in a very languid way, and without force; could not stand, nor even sit up, and was unable to hold her head up; there was one spot in the middle dorsal region which was slightly tender over the spinous process, and one spot in lumbar region where there was tenderness to the right of the spine; the spine was perfectly straight; the capillary circulation was very sluggish in the legs. All the muscles reacted to the faradic current. Sensation was very slightly if at all affected. The urine acid, 1014, albumen, about one fourth per cent. granular casts and

hyaline casts, some with granules; amount during the first fortnight six to thirty ounces daily.

She had iron, massage, electricity, and steam baths, and the urine increased in amount to from forty-eight to sixty-six ounces daily. November 12th and 13th there was retention of urine which hot bath or fomentation relieved, and the amount was temporarily diminished, but immediately after increased again to above fifty ounces. On October 23d there was no albumen, but a few hyaline casts could still be found. November 25th both albumen and casts had disappeared.

She slowly gained strength, and in January, 1878, began to sit up; she was able to walk nearly across the ward by the 1st of February, and was discharged April 3d, well. Since that date she has been several times heard from; she continued to gain strength, and more than two years after leaving the hospital she was well, and able to walk at least a mile without unusual fatigue. She has just been heard from, and is still gaining in strength, and remains healthy.

This seems to have been simply a case of overtaxing of the muscular and nervous system by a patient naturally weak, and not fully recovered from the debilitating effects of scarlet fever. Whether the albuminuria was cause or effect of the weakness I don't know. The lesions to be excluded in forming a diagnosis were caries of the vertebrae, in common with which there were scarcely any symptoms; myelitis could not be excluded so summarily, though the retained reaction to the faradic current would exclude poliomyelitis. An ordinary case of chronic myelitis has most of the features present in this case, but it would be extremely rare for myelitis to continue between one and two years, extending so as to affect the arms and the muscles which support the head, and yet the patient have power to move the legs so freely in bed. However, there was so much similarity to myelitis that it was not possible at first to say positively it was not that disease, but a short observation showed that it was probably functional. There was not sufficient tenderness over the spine to classify it as a case of spinal irritation. The result shows that it was simply functional weakness.

Annie W., aged twenty-nine, married, was sent into the City Hospital by Dr. Lyman; she had had four children, the youngest four years previously. For twelve years she ran a sewing machine, by foot most of the time. Two years before admission she had pain in both knees lasting about two months, otherwise no trouble till four months preceding entrance, then her head felt dizzy, memory failed, but she had no headache; her feet felt numb and cold as if ice water was running over them, the numbness extended, on admission, six or eight inches above the knees; she walked with difficulty, and said she had to watch the floor to tell when her feet touched it. For a few days before admission her hands felt numb.

On examination it was found that sensation was only diminished, not lost, was slightly retarded in legs and feet; the cutaneous reflex on tickling the soles of the feet was absent, patella tendon reflex was also absent; there was considerable impairment of motor power, she walked with difficulty, which was increased when her eyes were closed; hot water gave no unnatural sensation on the back; there was no tenderness on pressure over the back; there were a few crackling râles at the left apex, no difference on percussion.

Iodide of potassium was given, and after that had

been taken some time her urine was examined by Dr. Wood, who found no lead in it. The treatment consisted in the use of galvanism to the back, dry cupping of the back, and strychnia, increased up to one fifteenth of a grain. These remedies were used at different times, and changed according to the patient's condition. She slowly gained in strength, and when discharged was able to walk better, had less numbness.

She was seen two or three months after her discharge, and said she had no numbness in her legs, no stiffness, her arms were all right, and she walked perfectly well.

One element in the aetiology does not appear in the record,—she had taken care of her sick children before the commencement of her illness.

I was in much doubt as to the nature of the affection in this case. I thought it possible that there was simply functional weakness, but was rather inclined to believe there was inflammation of the spinal cord. It is of course possible that lead had been present, and caused the symptoms, but was all eliminated before the urine was examined. I am willing to let the case stand as doubtful, but am rather inclined to look upon it as functional.

These three cases differ in some respects, yet closely resemble each other. The first case is clearly one of spinal irritation, but there was more loss of motor power than is usually seen in that affection. It may serve to illustrate those cases of muscular weakness, possibly due to lesion of the muscular fibres, which are seen after acute fevers, more especially after typhoid. It is rather doubtful whether there was really spinal meningitis during the typhoid attack.

The second case seems to have been one of real nervous exhaustion following over-exertion. Perhaps the effects of this would have passed off soon, if she had not been kept on her feet as long as she could stand, and even longer. The albuminuria may have been simply a result of this weakness.

The third case was one of those doubtful cases where the symptoms might lead to a diagnosis of inflammation of the cord, yet it was probably functional disturbance.

One point in regard to etiology not yet noticed is deserving mention. In these, and in other cases, before the patients finally break down, there is usually some factor exerting an influence to lower the general health of the patient. This was so in the cases just reported. Two patients now under treatment suffered from sore throat just before the weakness appeared; in one of these at least it was not diphtheritic, as he was seen by a doctor fully qualified to judge.

The immediate cause of the occurrence of such functional weakness is sufficiently evident from the above histories; but besides bodily exertion, mental overwork is said also to be a cause.

The seat of the disorder may be either the muscles or the nervous system. Muscular fibres may be so overtaxed as not to recover their normal condition in the short time allowed for rest; they then undergo degeneration, or not being sufficiently recovered from fatigue are easily fatigued again.

When the nervous system is the seat of the affection, it is probably the cord which suffers, rather than the nerves. Erb says, in regard to these cases: "The most obvious view is that which supposes that the physiological fatigue of the nervous elements, which always occurs after severe and protracted irritation, becomes exaggerated and assumes a fixed form. In such a case we may suppose that the fatigue of the nervous elements does not become repaired in the prompt manner which is usual under physiological conditions."

The diagnosis between these cases of functional weakness and myelitis in its early stages is not always easy but is very important.

When there is great tenderness upon pressure over the spinous processes it is almost certain that the weakness is functional. The case is one of spinal irritation with accompanying weakness. I do not mean tenderness developed only by strong pressure, but where comparatively slight pressure evidently causes pain. Such patients may not readily recover, but there is no inflammatory change in the spinal cord rendering recovery impossible. I have seen several of these patients besides the one whose history I have reported, who have regained the power to walk, and are now walking about, some enjoying a very reasonable share of health.

The chief difficulty in diagnosis is to be found rather with the other variety of cases, where there is little or no tenderness of the spinous processes.

There will be a chance of mistaking these cases for incipient myelitis or for congestion of the cord; and it will sometimes be very difficult to come to a satisfactory conclusion. The principal diagnostic points to be noticed are that in functional weakness sensation is as a rule much less affected than in myelitis. There may be abnormal subjective sensations, as tingling or a sleepy feeling, but when tested it will be seen that the various sensations are at most only slightly affected. After quiet in bed or after ceasing active exertion the numbness of which many of these patients at first complain is very much diminished or wholly disappears. There is not real paralysis but motor weakness and the muscles are easily exhausted, and the patient may even sink to the ground from fatigue after a very short walk, and then the limbs may feel tired and heavy or may even ache hard. It is not often that so great weakness is seen as was present in the second case I have read.

The condition of the bowels and bladder cannot be depended upon for aid in diagnosis, as even in myelitis in the earlier stages these may not be affected, and in nervous exhaustion there may be slight disturbance.

The fact that there is no wasting of the muscles and that they retain their power of reacting to the faradic current will conclusively exclude an affection of the anterior cornua.

Though the patients may stagger some in walking from weakness and be unable to walk steadily with their eyes shut, generally, however, there is no difference in their power of walking whether the eyes are open or shut, yet there are no symptoms properly belonging to locomotor ataxia. The legs may ache, but there are no shooting pains in them, the tendon reflex is rather exaggerated than diminished if it is affected at all.

In some of the patients, even where there is no spinal irritation, the nervous system is so exhausted that the emotional element is prominent and the patients easily shed tears. This was especially so with a young girl whom I have lately seen, who overtaxed herself by walking to and from school.

As to treatment, it has been mentioned in the cases which I have reported, rest, electricity, massage, cupping to the back or perhaps actual cautery, iron, quinine,

and strychnia. I have thought in one case, as might be expected, that ergot was of disadvantage and the patient did not do well under it. It might be well to combine with other remedies systematic bathing, especially if it is not convenient to use massage.

It is well to take into account that recovery of strength is very slow, and treatment of severe cases must extend over months.

Erb, in Ziemssen's *Cyclopedia*, describes spinal nervous weakness, which comes as near to the cases I have reported as possible. I have not seen exactly the same grouping of symptoms in any other author, except Ross, who, with condensation, copies almost word for word from Erb.

C. H. Jones mentions several cases closely resembling these.

Other authors have described somewhat similar symptoms under spinal irritation, but these cases cannot all be classified under that title.

## RECENT PROGRESS IN CHILDREN'S DISEASES.

BY T. M. ROTCH, M. D.

### RHEUMATISM.

HIRSCHSPRUNG<sup>1</sup> reports a series of cases where there was a peculiar localization of acute rheumatism in children, characterized by swelling of the sheaths of the tendons, appearing outwardly as very pronounced little lumps, and he concludes his article by describing two cases. Case I. was a girl eight years old, who, after three weeks' complaint of pain in the knees and back, sometimes also in the other joints, accompanied by slight fever, presented, besides a slight left-sided pleuritic effusion, small hardish deposits arranged in a row along the tendon of the palmaris longus muscle, and also similar prominences, excepting that they were larger, where the tendon of the extensor communis muscle and extensor longus pollicis pass over the wrist. They were bilateral, symmetrical, and moved with the tendons. Similar swellings appeared on the outer sides of both ankles, and also on the tendons of the left peroneus, extensor communis, and extensor hallucis longus: also numerous rings around the knee-joints, where they were as large as peas; they were also found near the spinous processes of the vertebrae. In the course of a month, during which several of the finger-joints were slightly swollen and heart murmurs developed, these swellings retrograded and disappeared entirely. One and a half years later the child was again seen, and found to have mitral insufficiency and pericarditis. A few days afterwards swellings of the same character as before observed appeared on the spinous processes, and later on the tendons of the hands and feet. Then fever developed, and after several days, improvement and retrogression of all the appearances, even to the systolic apex murmur.

Case II. was a girl three and a half years old, who was attacked with fever, wandering pains, passing finally into swelling of the backs of both feet, but without swelling of the joints, and after two weeks getting well. Soon, however, the little patient again complained of pains, became feverish, developed swelling of different finger-joints, and during this relapse an endo-pericarditis. She was then pretty well, excepting that the heart trouble continued, for two

months, when she left the hospital, but returned in five months with the valvular disease much increased, and on the points of both olecranon a cartilaginous spur-like body, not painful, and movable under the skin. The child soon died. The autopsy showed old and fresh pericarditis, myocarditis fibrosa, traces of fatty degeneration, pigment atrophy, and old and fresh endocarditis. On either side of the olecranon were found bodies the size of a pea, directly upon the triceps tendon, and consisting of connective tissue, with flat and spindle-shaped cells, and here and there round, large, nucleated cells, besides richly distributed and partially dilated vessels, of which individual arteries at times showed a most striking thickening of their muscular coats.

The writer also speaks of similar observations made on a girl twelve years old and a boy nine years old.

### INCUBATION PERIODS.

The incubation of infectious diseases is a subject of interest and importance, which is rendered difficult to determine definitely by the exceedingly few opportunities which physicians have for making personal observations, not dependent on the usually untrustworthy reports received from the laity; the investigations of Dr. Clement Dukes,<sup>2</sup> physician to Rugby School and Hospital, are therefore especially noticeable from the unusual means at his disposal of ascertaining the incubation period of scarlatina, varicella, mumps, and röteln. Dr. Dukes reports his observations as follows, prefacing his remarks by the statement that the incubation cannot always be accurately calculated within twenty-four hours, from the first case not being seen at the very beginning, or from its being seen on the evening of one day, and the next case in the morning. He also states that the immediate isolation of each patient made it impossible for that patient to be a source of infection after the first few hours.

### SCARLATINA.

He first speaks of scarlatina, epidemics of which occurred during the years 1877, 1879, and 1881. The number of cases in each epidemic was necessarily small, from the fact that early isolation was immediately resorted to, but there were fifteen cases in all, and the following table represents the number of days of the period of incubation:—

| Cases. | Days. |
|--------|-------|
| 1      | 1     |
| 3      | 2     |
| 2      | 3     |
| 4      | 4     |
| 2      | 5     |
| 1      | 6     |
| 1      | 9     |

Thé report of the manner in which B. S., one of the cases where the time of incubation was four days, was infected it may perhaps be interesting to note. The school assembled May 2, 1879; A. W. was attacked with scarlet fever (probably caught on the journey from home) May 7th, and was isolated almost immediately. B. S. (just before A. W. was removed) had some hot words and "head in chancery" with A. W., because the former had hit A. W.'s little brother. Otherwise they never had had any communication with each other, either in bed-room, school-room, or dining-room. Two of the cases of scarlatina had variella

<sup>1</sup> Jahrb. für Kinderheilk., N. F. xvi., S. 324.

<sup>2</sup> The Lancet, October 29, 1881.

at the same time, occurring on the tenth day from the first appearance of the scarlatina.

#### VARICELLA.

Careful observations were made on fifteen cases during an epidemic of varicella, with the following results:—

| Cases. | Days of Incubation. |
|--------|---------------------|
| 2      | 14                  |
| 3      | 15                  |
| 1      | 13 or 14            |
| 1      | 14 or 15            |
| 2      | 14 or 16            |
| 3      | 16 or 17            |
| 1      | 17 or 18            |
| 2      | 19                  |
| —      |                     |
| 15     |                     |

#### MUMPS.

| Cases. | Days of Incubation. |
|--------|---------------------|
| 1      | 14                  |
| 1      | 15                  |
| 3      | 16                  |
| 6      | 17                  |
| 8      | 18                  |
| 9      | 19                  |
| 4      | 20                  |
| 1      | 21                  |
| 1      | 22                  |
| 1      | 23                  |
| 2      | 24                  |
| 1      | 25                  |
| 1      | 17 or 19            |
| 1      | 18 to 20            |
| 2      | 20 to 22            |
| —      |                     |
| 42     |                     |

#### THE ORCHITIS OF MUMPS.

Dr. Dukcs states that his observations lead him to believe that the orchitis of mumps is not a metastasis, but a complication of mumps that can be watched for; it comes neither before nor after a certain definite time, and it comes only in certain cases, namely, those who have arrived at or beyond the age of puberty, although unfortunately the ages of the patients were omitted in the report. This fact of age is a great guide to treatment, for by keeping all likely cases in bed until the ninth day, and carefully taking the temperature, which rises before the pain is felt, and on the slightest rise of temperature applying a hot poultice to the testicles, the severe pain is mitigated, and the acute general symptoms are diminished by the patient being placed thus early under general treatment. Only one of the cases of orchitis behaved abnormally, and in this case the orchitis took the place of the parotid swelling on the first day, and the parotids were not touched from beginning to end, but only the submaxillary glands, and in this case the symptoms were very severe. In two of the cases there was acute delirium, and one of them was followed by hydrocele, paracentesis, and subsequent atrophy of the testis. In one of the cases the patient fainted when the orchitis began.

| Cases. | Number of Days from beginning of Mumps. |
|--------|---|
| 1      | 1                                       |

#### RÖTHELN.

Dr. Dukcs claims to have seen an unusually large number of cases of rōtheln, and as there is still a great difference of opinion as to what the nature of the disease and its clinical picture is, as well as whether such a distinct disease exists, he very wisely precedes his article on this subject by citing what he means

in speaking of a mild case and of a severe case of rōtheln.

(1.) Mild case. A boy presents himself to me. "Please sir, I've got a rash, and I had better show it to you, although I feel perfectly well." I examine, and may see a few tiny spots; or a few larger spots or blotches of a rosy hue; or a diffuse rosy hue in one part, as at elbows and knees, and spots or blotches in other parts, generally on face and hands and arms first. A warm bath and bed develop more rash; no headache, sometimes sore throat or reddish eyes, but mostly not; pulse 80 and temperature 99° F. in the evening, normal in morning. The rash may be all gone in the morning, or may last, coming out in one part, going in another, for a day or so; then it all goes, and is not followed by peeling. The patient feels hungry throughout, and not ill in the least. After about three days in bed, followed by four days of fresh air, he is washed from head to foot with carbolic soap, his clothes are put through the disinfecting chamber, and he returns to school.

(2.) Severe case. A boy complains of headache and general malaise, slight sore throat, loss of appetite, and drowsiness; looks heavy; eyes red; no catarrh, but a little cough sometimes; slight redness of fauces; skin on exposed parts raised in appearance, but no actual rash; quick pulse and increased temperature. He has a hot bath and is put to bed, when a rash gradually appears on exposed parts first, papular in character, and gradually intensifies in color, so that it becomes of the brightest rosy hue (not dusky); these papules become blotches and gradually spread all over the body until he is in one mass of eruption, sometimes with scarcely any intervening natural-colored skin. The rash that came out first gradually fades while the rest is appearing, and the whole process lasts three or four days or more. The eyes and the whole mucous membrane of the mouth and fauces look red, but there is no catarrh; the tongue is coated. Pulse 120 or more; temperature 103° F. or 104° F.; great malaise; all symptoms gradually subside, and the rash is followed by roughness of the skin. After isolation for fourteen days he is thoroughly disinfected, and returns to school.

Dr. Dukcs considers rōtheln a distinct disease *sui generis* and decidedly infectious: it varies greatly as to character and severity, sometimes presenting no symptoms beyond the rash, again making the patient quite ill; the rash also varies very much in its amount and color. One attack apparently protects from a second. It is unattended by sequelæ. There is a rash produced by certain caterpillars, with which boys and girls are very fond of playing, which so much resembles the beginning of rōtheln that it occasions a great deal of trouble, when rōtheln is about, from the uncertainty as to whether you have only a caterpillar rash or rōtheln to deal with. The oak-egg, or bombyx quercus, the liparis aurilua, the arctia caja and arctia villica, and the common drinker, odonestrus potatoria, are the chief creatures. Wherever they crawl, or wherever the fingers go that have touched them or cleaned out their cages, there we get a measly rash. As a rule it begins on the fingers; then the eyes are rubbed, and we see measly-looking eyes; then they scratch their faces and necks, or any part of the body, when we here also get a rash. So common is this in early summer that he always has it in mind in making a diagnosis.

Infection appears to take place in the very beginning of the disease, so that isolation seldom prevents its spreading, but the following twenty-three cases were carefully isolated and the incubation period noted:—

| Cases. | Number of Days of Incubation. |
|--------|-------------------------------|
| 1      | 12                            |
| 1      | 13                            |
| 1      | 14                            |
| 2      | 15                            |
| 4      | 16                            |
| 1      | 20                            |
| 1      | 22                            |
| 1      | 13 to 15                      |
| 1      | 14 to 16                      |
| 3      | 15 to 17                      |
| 3      | 16 to 18                      |
| 23     |                               |

The subject of the recognition of *rötheln*<sup>1</sup> as a distinct disease was thoroughly discussed in the section of the International Medical Congress devoted to diseases of children, and the remarks of Dr. Jacobi, of New York, on this question are especially worthy of record. Dr. Jacobi said that the difficulty in diagnosis must be great in many instances, as the description of cases given by the best authors varied much. The difficulty was greatest with those in large cities, when and where, as a rule, there were complications of allied epidemics. During the prevalence of any infectious disease everybody was to a certain extent under its influence. Thus, during epidemics of diphtheria, scarlatina, erysipelas, cholera, everybody was liable to be taken on slight provocation, or, at all events, to exhibit some of the symptoms. Thus pharyngitis and cervical adenitis were very common among persons who were considered well. In this way he explained the fact that symptoms not belonging at all to *rötheln* were mentioned among its symptoms. In large institutions, distant from large cities, and remote from epidemics of measles and scarlatina, *rötheln* had been observed as a distinct disease, to be very contagious, and very slightly febrile, no cases, or very few, being attended with throat symptoms or adenitis, the eruption resembling measles more than scarlatina, convalescence being absolutely safe and easy, and desquamation, if occurring at all, very trifling and furfuraceous.

The president of the section, Dr. West, closed the discussion by remarking that the evidence brought forward by the speakers almost amounted to a demonstration that *rötheln* was a distinct disease. In its incubation period it differed markedly from scarlet fever, but approached that of measles, which, however, it usually exceeded. It differed from scarlet fever in the absence of severe throat symptoms, in the character of the rash (a point, however, not to be appreciated in the first twenty-four hours), and in the fact that it was usually a mild disease, not followed by sequelæ.

Sydenham had written on the epidemic constitution of disease, and in this connection the remarks of Dr. Jacobi on the influence of epidemics in modifying the health of people and the course of other maladies deserved to be borne in mind.

#### CONGENITAL BRONCHIECTASIS.

Dr. Paul Grawitz<sup>2</sup> reports the examination of a number of cases of bronchiectasis found in the fetus, and one case in a child one year old, and concludes that congenital bronchiectasis is caused mechanically by an accumulation of fluid in the fetal lung.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY.

#### SECTION FOR CLINICAL MEDICINE AND PATHOLOGY.

ALBERT N. BLODGETT, M. D., SECRETARY.

DECEMBER 12, 1881. The meeting was called to order at eight o'clock. On motion of Dr. R. M. HODGES, Dr. T. B. Curtis was elected chairman. Dr. Curtis not being present, Dr. S. L. Abbott was elected chairman *pro tem*.

Communications were received from Drs. Minot, Tarbell, and Whitney, who were unable to be present. After the reading of the records of the previous meeting a paper was read by Dr. H. I. BOWDITCH upon

#### TWO FATAL CASES OF PLEURISY. See p. 48.

Dr. HAMILTON OSGOOD said that he could merely indorse all that Dr. Bowditch had said in regard to the great necessity of promptness in the performance of the operation of paracentesis in acute pleurisy. One of the cases which Dr. Bowditch had detailed had been a sad lesson to him. He had asked that the operation might be performed on the day on which the practitioner in question had taken charge of the case. The latter objected, on grounds mentioned in Dr. Bowditch's report. The fame of the practitioner was world-wide. There was no higher authority in his own country. He was not unfamiliar with the operation, having performed it for many years. Under the circumstances nothing more could be said. The cause of such sudden death in a case of pleuritis which apparently was doing well is a matter of deep interest. Bartels has asserted and proved by several autopsies, so also has Fraentzel, that in these abruptly fatal cases the affection is always unilateral and left sided, as in this case, and that the large effusion causes a rectangular twist in the ascending vena cava; Trousseau thought more especially in the aorta. The effect of this condition is the more dangerous because, according to Fraentzel (1) a sudden increase in the amount of the effusion is accompanied by a corresponding diminution in the whole mass of the blood, and (2) the effusion still further compresses the affected lung, the loss of whose vital movements restricts and interferes with the passage of blood from the right to the left heart. If under these circumstances there occurs a transitory and accidental disturbance of the circulation, as in a hasty movement of the body (which was the case in the patient under discussion), or a fit of coughing, the arterial blood pressure becomes absolutely insufficient, and this is quickly indicated by syncope or immediate death. Fraentzel relates a case of left-sided pleuritis which came one evening into his wards in the Charité in Berlin. He saw that paracentesis was necessary, but deferred it until morning. During the night the man suddenly expired. The autopsy revealed a twisted vena cava ascendens. Fraentzel speaks of the case as an impressive lesson, teaching that not an hour should be lost in doing the operation wherever it seems necessary. In these cases of fibrous effusion he uses cups when the fever is high and the effusion is rapidly increasing. He advises paracentesis when the quantity of effusion is large and absorption is slow. Dr. Walshe says that the period at which paracentesis is most likely to afford permanent relief is easily suffered to pass by from procrastination,

caused by the natural desire to give gentler measures a full trial. Judging from his own experience, sudden syncope in acute pleurisy is a very rare occurrence, but he advocates early operation when the effusion is large.

In regard to the jelly-like mass found in the effusion, in the case under discussion, the speaker thought it could not have existed in such bulk ante mortem, and therefore would have been no hindrance to the operation. Virchow mentions a case as "peculiar" in which a serous effusion, issuing from the chest as a perfectly clear fluid, shortly after exposure to the air had its whole mass pervaded by a coagulum. This "phenomenon," he thinks, is difficult of explanation on the supposition that real fibrine existed completely developed in the fluid. He says that the coagulation indicates the presence of a substance nearly related to fibrine, but not real fibrine, and which requires the contact of atmospheric air for its conversion into true fibrine. He therefore gave it the name of *fibrinogenous substance*.

The speaker thought that during the time occupied in the post-mortem examination of the heart of the patient mentioned by Dr. Bowditch sufficient time elapsed for coagulation of the pleuritic effusion through contact with the air.

In conclusion, he said that in the treatment of this case common sense would have led to a prompt performance of paracentesis. No one can say, no one has a right to say, the patient would have lived, but his chances would have been infinitely better. In any case of acute pleurisy the practitioner should never visit his patient without a trocar in his pocket, and it would be wise to have the proper instruments for paracentesis kept in the house of the patient ready for instant use.

DR. A. T. CABOT wished to say a word in regard to the propriety of making occasional use of the more radical operation by free antiseptic incision and drainage in purely serous effusions.

"In the majority of non-purulent effusions repeated aspiration is usually successful in checking the accumulation and accomplishing the final absorption of the fluid. Occasionally, however, we meet with an effusion which reaccumulates with great rapidity after removal, and allows the compressed lung but little time to recover itself before it is again disabled by the returning pressure.

"Under these circumstances the relief to the patient after aspiration is of short duration, and does not enable him to gather strength to shake off the disease. Of such character are many of the fatal cases of pleurisy.

"If, now, in a case of this sort a free incision is made, and reaccumulation thus rendered impossible, the immediate danger of death from the pressure of the fluid upon the heart and sound lung is avoided, and the lung of the affected side is allowed time to recover itself, and is thus not disabled for future use. The success attending the treatment of other serous effusions (hydroceles, etc.) by antiseptic incision, and the good results attainable by this method in cases of empyema, would encourage one to employ it in cases of simple pleurisy which resisted less radical measures and threatened life.

"A little more than a year ago I saw a man of about sixty in an almost moribund condition, cyanosed, with respiration about 70, pulse 140, barely perceptible. The right side of his chest was flat throughout. I drew off two and a half pints of serum with an aspira-

tor, and stopped then only because he was beginning to cough. This operation was followed by considerable relief; the respiration and pulse fell, and his strength improved somewhat.

"Within the next month I was obliged to draw off fluid six times for the relief of dyspnoea. Each time the relief following the operation was less than before; and the patient, who had at first gained, finally began to lose strength again.

"Believing that in such a case a free incision was called for permanently to relieve the intrathoracic pressure, I operated antiseptically and inserted a rubber tube. The patient recovered well from the operation, which was followed by little or no fever, and seemed for a few days to be doing fairly well. But on the sixth day after the operation he failed rapidly and died. In my absence Dr. M. H. Richardson attended this patient for the last few days of his life, and said that the fluid always remained purely serous, without a drop of pus. It seemed to both of us that the death could not be at all attributed to the operation, and that had our patient been less enfeebled by the previous long and exhausting course of the disease we might have justly expected a favorable issue. This belief has since been confirmed by the favorable course of a similar case which I saw in consultation with Drs. Bowditch and Richardson, in which a free opening has been followed by steady improvement in what was at first a very unpromising case.

"In conclusion I would like to say one word about the application of the antiseptic dressing in these cases of free opening of the chest. I consider the proper application of the mackintosh of the greatest importance in hastening the expansion of the lung.

"This water and air proof layer of rubber cloth should overlap the loose gauze next the tube, so that its edges reach beyond the underlying gauze and are applied closely to the chest wall. They are then held firmly against the skin by the elastic dressings over them. Now at every cough, sneeze, or other forcible expiration, the air will be driven out of the chest and will escape from under this edge, which acts then as a valve to prevent its return. The air in the pleural cavity is thus constantly diminished, and the organs, if not held by adhesions, rapidly resume their normal positions.

"In a case which I operated upon last summer the heart was upon the right of the sternum before operation, but on the following morning, when the first dressing was changed, had resumed its normal position, and the respiration was to be heard nearly, if not quite, to the base of the chest."

DR. F. C. SHATTUCK remarked that during a winter he had passed in Vienna, eight years ago, death from uncomplicated pleuritic effusion was not uncommon. He remembered distinctly the criticisms on this very point of a medical friend and unusually good observer, who regularly attended the autopsies in the Vienna General Hospital, and who, during a period of a few months, saw five or six cases in which death was caused directly by large effusion. Aspiration was at that time but little practiced in Vienna, and the first assistant of Professor Ducheck said to Dr. S. one day, in talking of the operation, "We have not had much success with paracentesis here." In this neighborhood, and indeed in this country, accidents of this nature seem to be very rare.

As regards Dr. Bowditch's question whether American students in Germany would not do well to place

themselves in the hands of their compatriots in case of illness, Dr. S. said that with full knowledge of the case reported by Dr. Bowditch and of a Vienna case, in which the treatment had not seemed to him wise, soon after his arrival in that city he had agreed with a medical friend that if one fell sick the other should take entire charge of the case.

Dr. S. also alluded briefly to a case which he had aspirated that same morning, and obtained about two ounces of apparently clear blood. (This case will be reported more fully later.)

Dr. F. I. KNIGHT coincided entirely with the reader, and thought there would be no difference of opinion among American practitioners in regard to the treatment to be instituted in a similar case. He could see how, in considering the propriety of operation, one point would naturally receive more attention in Europe than in this community, namely, the danger of thoracentesis, as deaths had been reported there which had been attributed to the operation, while none such had occurred here; our foreign brothers balanced the danger from the operation against that of sudden death from the effusion. Another cause of sudden death besides the twisting of the vena cava ascendens is embolism from thrombosis of the pulmonary veins; also oedema of the opposite lung. The danger in the operation seems to arise from the dislodgment of emboli, sudden syncope, and oedema of the opposite lung. Emboli, if formed, would probably be detached on the natural expansion of the lung, and aspiration would only hasten their dislodgment. So, early tapping, before thrombosis occurs, may prevent this evil. Syncope and oedema may be produced directly by the operation, which should therefore be very guardedly and slowly performed. The causes of sudden death in case of pleuritic effusion, as well as the causes of sudden death during or after paracentesis, demand further investigation.

Dr. GARLAND thought that the chief danger of thoracentesis lies in a too rapid evacuation of the fluid. It is obvious that the sudden expansion of a collapsed lung, and the violent reposition of a displaced heart must produce a great impression upon the system, and if, perchance, any clots have formed in the circulation, the rapid stretching of the vessels must favor embolic accidents, whereas a more gradual and gentler method will accomplish the desired end without objective injury or subjective discomfort. The French have written much about the dangers of this operation, and have enumerated a multiplicity of possible accidents, and one need not wonder that they do have such accidents when one sees the instruments which some of them use. Dr. Garland described one French aspirator which was as large in diameter as his arm, and was placed upon a heavy base, at an angle of forty-five degrees, like a bomb mortar. The piston was armed with a ratchet, and was drawn up by a cog-wheel, whereby a very powerful vacuum was produced. The stream which flowed out of a chest into such an instrument was terrifying by its force and rapidity. Such a barbarous engine could tear a heart back into place and stretch open a lung with destructive energy. Dr. Garland said that the siphon method of aspiration was the most gentle in cases where it could be used. Here the force is constant and of moderate degree, being the negative pressure of a column of water about two feet in height. In employing the Dieulafoy aspirator Dr. Garland uses the smallest vacuum which

will keep the stream flowing. By removing slowly one has plenty of time to notice the slightest expression of discomfort on the part of the patient, and arrest the flow before any danger has occurred.

In regard to the amount which should be removed at one sitting, Dieulafoy says that one thousand to twelve hundred grammes are the outside limit. He claims that all the accidents reported have followed the withdrawal of large amounts of fluid, from three thousand to five thousand grammes. Dr. Garland believed that the rapidity of the withdrawal was much more important than the amount. Recently, in a case of large effusion in a sailor, Dr. Garland removed eighty-four ounces (2688 grammes) of fluid by the siphon method. The operation lasted about one hour and twenty minutes, and therefore the fluid escaped at the rate of about one ounce per minute. During this time the elevation of the diaphragm, the gradual expansion of the lung, and the replacement of the heart could be followed inch by inch, while the patient experienced absolutely no discomfort. He expressed only relief when questioned. The lung could be felt against the inner end of the canula when the operation was ended.

Five days later Dr. Garland removed from the same patient eighty-eight ounces (2816 grammes) with a Dieulafoy aspirator. This operation was performed in thirty minutes, that is, about three times as fast as the previous one. At the conclusion the patient complained of slight uneasiness, and was seized with coughing, which required some effort for repression.<sup>1</sup>

The fluid removed at the first sitting did not coagulate even after standing in a basin for an hour. At the second sitting the effusion became solid in about ten minutes after withdrawal. Dr. Garland was unable to explain this striking difference in the behavior of the two fluids.

Dr. M. H. RICHARDSON remarked, with regard to the danger of sudden death in removing fluid from a distended pleural sac, that there seemed to him to be less in making a free opening than in the use of the aspirator. In the latter operation the displaced thoracic viscera are crowded back towards their normal position by the great force of atmospheric pressure. It is evident, if the heart and lungs are prevented from yielding to force, that there will be great distress and serious disturbance to these organs. In case of a free incision on the other hand fluid will escape until the intra-thoracic pressure is relieved and there will be no further traction on the thoracic contents, the remaining fluid slowly escaping as air is allowed to take its place. Sudden and violent changes in the position of the heart and lungs being thus avoided we certainly escape one of the dangers of sudden death.

The value of rigid antiseptic precautions in thoracic surgery Dr. Richardson thought very great, and he agreed with Dr. Cabot in saying that the importance of these measures cannot be overestimated.

The treatment of certain cases of pleuritic effusion by free aseptic drainage as proposed and carried out by Dr. Cabot, is a new procedure in the surgery of the chest, and one which must depend for its success on the most rigid and thorough application of the theory of antiseptic dressings in all its details. In the two cases of this kind which the speaker had seen, and which so far as he knew were the only ones in which this treat-

<sup>1</sup> The effusion did not collect again, and the sailor has since made two fishing trips.

ment has been carried out, the results seemed very clearly to demonstrate the value of the so-called Listerism. In the first case under Dr. Cabot the discharge from the pleural cavity remained not only inoffensive and sweet but purely serous as long as the man lived. In the second case, under Dr. Richardson, the discharge continued perfectly serous for fully three months, during which time the patient advanced from a state of extreme exhaustion and impending death, where repeated aspirations were of no permanent relief, to a condition of comparative comfort and usefulness.

Dr. J. A. McDONOUGH was called to a case at the north end. Patient, aged fifty, was sitting up in bed. Inspection showed bulging of intercostal spaces. There was dyspnoea. A large trocar and canula were plunged into the chest, and an ordinary Davidson syringe was attached, and after a large quantity of fluid had voluntarily run out pumping was employed until the patient complained of distress. The amount of fluid withdrawn should be regulated by the feelings of the patient.

Dr. LIEBMANN said that during his residence in Germany he had often seen thoracentesis performed in cases of pleuritic effusion. Griesinger did the operation twenty-five years ago, and cases are constantly reported. The danger is that the operation is much too frequently employed by German practitioners.

Dr. OSGOOD said that Fraentzel, who has written the most recent German monograph on pleurisy, asserts that although Traube for many years made frequent use of paracentesis in fibro-serous effusions (in which sudden death occurs), the German practitioners, in general, in this class of cases, even to this day, use it but little, and this in spite of the teachings of Dr. Bowditch, Trousseau, Dieulafoy, and others who have shown the safety and success of the operation in hundreds of instances.

Dr. BOWDITCH said that the heart is often greatly displaced, sometimes as far as the level of the third rib on the right side. A permanent opening is demanded in cases in which the lung does not expand. In the case reported by Dr. Cabot Dr. Bowditch thought the patient was "doomed" before the operation was performed.

In one case there was a continuous moderate discharge of pus from the chest, but the patient did not improve. On washing out the chest a vast quantity of additional purulent fluid was removed, which was followed by recovery. Dr. Bowditch asked Dr. Knight why so many cases of death from thoracentesis are reported from Germany. Dr. Bowditch has never seen a case. He always terminates the operation when there is the slightest distress. He asked the meeting if any member knew of a case of death from this operation.

Dr. KNIGHT said that most of the accidents connected with the opening of the chest are reported by French practitioners.

Dr. BOWDITCH said that he went to Europe in the early days of thoracentesis and explained the operation and exhibited the instrument for performing it to Louis, who did not consider the operation feasible. He then went to Vienna and was treated with contempt by Skoda.

Dr. F. H. WILLIAMS exhibited an ingenious appliance for evacuating fluid from the chest or for washing out the pleural cavity, which will be described and illustrated in a future number of the JOURNAL.

# SPONGILLA.

Dr. HENRY J. BARNES exhibited some of the vegetable mould which has been deposited in Farm Pond and which was at that time undergoing rapid changes. He also showed the *Spongilla* found by Professor Remsen in this water. Dr. Barnes' remarks formed the outline of a paper he is preparing upon the impure condition of our present water supply. He claimed to be able to show that the water of Sudbury River was good before the recent basins were constructed, this water being extensively employed for bleaching purposes at that time. He asserted that Farm Pond water was good, and that this basin required little work, as was also asserted by Mr. Davis, the former City Engineer. The trouble has been occasioned by the imperfect method of construction of basins No. 2 and No. 3.

The *Spongilla* in Farm Pond finds its nourishment in the organic matter brought hence from those imperfectly constructed basins. The "pig-pen" taste and smell of No. 3 is due to decomposition of organic matter and shows where this matter has gone. He claimed that Mr. Norman made a mistake in smelling this vegetable mould in open air, to detect a disagreeable odor. He also asserted that the loam in these basins is now of comparatively little value for tillage or agricultural purposes.

Adjourned at 10.30 p. m.

# PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

JANUARY 9, 1882. Dr. C. D. HOMANS presided. The committee appointed to consider and suggest some appropriate form of memorial to the late President of the Society, Dr. T. B. Curtis, reported that they would recommend that a portrait of Dr. Curtis by Mr. Vinton be painted for the Society and deposited in the hall of the Medical Library.

The report was accepted.

# CONTRACTION AT THE HIP-JOINT.

Dr. E. H. BRADFORD read a paper entitled Cases of Contraction of the Hip-Joint. Vide page 52 of this Journal.

Dr. CHARLES PUTNAM said that he had not realized how much improvement had taken place in the case of the young woman spoken of by Dr. Bradford; he described how tired the patient formerly got on walking; she managed to get along by pressing the left knee against the right, thus keeping her centre of gravity; she walked, so to speak, first with both legs and then with the well leg. He considered that the essential point in the treatment was the great improvement in regard to ease in walking.

Dr. H. W. WILLIAMS spoke of the treatment carried out by Hewitt, which he had had an opportunity of observing personally. The affected joints were first placed in hot water impregnated with herbs and then very considerable traction was used.

Dr. POST repeated the description of a case just published by Dr. C. Fayette Taylor, of New York. It was the case of a physician, the victim of old hip disease, who had worn a very high patten.

Under the manipulations of Dal Cin his leg was reported to have been brought down to the same length as the other, and he had laid aside the high shoe. It was a case which excited a good deal of attention, and was the means of sending many patients to undergo the same treatment. The gentleman allowed Dr. Taylor to examine him, and Dr. T. found the hip-joint immovable and flexed at nearly a right angle. It was true that the leg could be brought down to a level with the other, but it was as usual in such cases at the expense of a curve in the lumbar vertebra, though the patient himself supposed the motion was in the hip-joint. To make his back rest naturally upon the table it was necessary to draw the affected leg upwards nearly to a right angle which would not be the case if there were normal motion at the joint. In walking his spine maintained the same curve, or at times he assisted in compensating for the deformity by bending the knee of the other leg.

DR. GRAHAM, who was present by invitation, said that the author of the book, *On Bone Setting So-Called*, to which Dr. Lyman referred, was Dr. Wharton P. Hood, of London. Hood states that the cases which bone-setters benefit by breaking adhesions are those of joints in which there is a slight degree of mobility checke by pain, a spot tender on pressure and an absence of acute disease. These symptoms, Dr. Graham remarked, are also found in joints in which there are no adhesions; for an increased involuntary tension of the muscles occurs in joints that are injured or diseased, which the force of habit often causes to continue after the joint is well. This involuntary tension<sup>1</sup> keeps the joint in an irritable condition and limits passive motion, hence the above symptoms. In some cases it is sufficient to explain to them that they may relax their muscles by repeated voluntary effort; in others massage with gentle, persuasive, passive, motion will greatly aid recovery. Later, to strengthen the muscles and to teach the patient how to use them, gradually increasing resistive motion is of value. It is a mistake to suppose that violent rubbing is of use in such cases, it begets reflex contraction of the muscles, increasing the evil it is intended to remedy, it causes an intense hyperæmia and hyperæsthesia of the skin besides chafing it. To avoid the last objection and to conceal the sufferer's ignorance oily substances are made use of.

Dr. Graham has used vigorous passive motion in several cases, notably in three cases of stiff ankles resulting from fractures of the lower end of the tibia extending into the ankle joint. The adhesions were heard and felt breaking, the pain was momentary, and two of the cases could walk immediately after without crutches, the freedom of motion in the joint being doubled. The third walked lame without any support before Dr. G. saw the case. Though some adhesions were broken but little increase of motion was gained; the improvement in walking and in going up and down stairs was much greater than one would have thought possible from the slight increase of motion in the joint. In this last case adhesions within and without the sheaths of the tendons may have been loosened by the accompanying use of massage. In such cases excellent preliminary measures to the break-

ing of the adhesions are a warm bath followed by the soothing influence of gentle stroking of the joint and limb, and by deep manipulation (without slipping of the fingers), which has a decidedly anæsthetic effect. Gentle tentative passive motion may then be tried so as to judge of the state of the joint and the amount of force to be employed. After the violent passive motion, deep kneading and a tolerably tight bandage increase the patient's comfort. When necessary Dr. G. has found that repetitions of these efforts are better tolerated than the first in suitable cases.

DR. WEBBER read a paper on

#### PARAPLEGIA FROM FUNCTIONAL WEAKNESS.

Vide page 54 of the JOURNAL.

DR. C. D. HOMANS asked if the variety of paralysis spoken of by Dr. Webber was similar to that which occurred in diphtheria.

DR. WEBBER replied that in a large number of cases of diphtheria it was so, but that in some there is a loss of electrical action and some evidence of disease of the cord.

DR. FIFIELD reported a case of typhoid fever of somewhat unusual type, occurring in a young man, twenty-four years of age. He had passed through the usual course of the disease, and was considered convalescent, being up and about his room; he then had, on the twenty-ninth day, a relapse, and was in bed until the sixty-seventh day, when he was again up and about his room, talking, and on that day eating some partridge; on the sixty-ninth day from the beginning of the disease he had another relapse, with high fever, delirium, and rapid pulse; the temperature was 105° F.; the tongue was dry; there was sordes, tympanitis, and a dusky rash on the abdomen resembling typhus more than typhoid, excepting that it was more distinct than is seen in typhus; there was subsultus tendinum, and the patient was unconscious.

Musk was given in suppository once in eight hours, and the symptoms were somewhat ameliorated. Albumen appeared in the urine on the seventy-sixth day, and small doses of morphia were then substituted for the musk. It was noticed that when he had a large fecal dejection the temperature went down a little, and the pulse, which averaged 150, was reduced to 130; these symptoms continued to the seventy-eighth day, when he was found to be violently delirious, snapping like a dog at the attendants. Soon after he had a violent convulsion, and in a few minutes another, which was followed by an immense fecal dejection, after which the serious symptoms rapidly passed off, he became conscious, and is now well excepting that he is still weak.

DR. FIFIELD also reported the case of severe hemorrhage of the cord, which was finally controlled by the application of plaster of Paris, and he exhibited the cast which was finally taken off, and which contained part of the cord.

DR. BOLLES reported a case of a man seventy years old, and previously considered to be in good health, who, after retiring to bed apparently as well as usual, was attacked with extreme orthopnea so that he could scarcely speak, and in about ten minutes he died, the whole course of the attack only lasting about three quarters of an hour.

The autopsy showed the heart to be normal, and no blood clot as a cause of death. The lungs were ex-

<sup>1</sup> The opposite condition, namely, relaxation, may be found after joint injuries. Two cases illustrative of these different states and the beneficial effects of massage upon them, Dr. G. has reported in full in the *New York Medical Record*, August 18, 1877.

trremely œdematous, and the kidneys were in a state of advanced interstitial degeneration.

DR. WARREN spoke of the treatment by emetics in these cases of œdema of the lungs, and mentioned the prompt relief by this means of a case where the patient was almost moribund, reported to him by the late Dr. Curtis.

DR. BOLLES also mentioned a case of asthma occurring in a child two years old, who had been subject to previous attacks of asthma for several months. In this attack an emetic was given with some relief, but in about half an hour afterwards the child became purple, and almost ceased to breathe; the child was completely etherized, and recovered from the attack.

## Recent Literature.

*Essentials of the Principles and Practice of Medicine.* A Hand-Book for Students and Practitioners. By HENRY HARTSHORNE, M. D. Fifth Edition, thoroughly Revised and Improved, with One Hundred and Forty-Four Illustrations. Philadelphia: Henry C. Lea's Son & Co.

The last edition of this book appeared in 1874, since when there have been many changes in various departments of medicine. These are reflected in the increased size of the book. Several hundred brief additions have been made throughout its pages, a number of new subjects receive attention, especially in connection with the pathology of the nervous system, the illustrations have been added to, and there is a new section upon eyesight, its examination and correction.

This volume, without ceasing to be in fact as well as in name a hand-book, certainly contains a great deal of matter, and is a very good example of the class of books it represents.

*Students' Aids Series.* Aid to Diagnosis. Part III. What to Ask. By J. MILNER FOTHERGILL, M. D. New York: G. P. Putnam's Sons & Co. 1881.

This is the second contribution by Dr. Fothergill to the Aids to Diagnosis of the Students Aids Series, and his third to the series itself. Part First of the Aids to Diagnosis on Semiology was from his pen, as was also the Aids to Rational Therapeutics. He seeks in the present number of the series to show the student and young practitioner how to put questions to patients so as to get at the chief features of a disease easily and methodically. If its readers succeed in catching the agreeable and sprightly manner of the writer they will no doubt find their profit in it.

*A Manual of Organic Materia Medica.* By JOHN M. MAISCH, Phar. D. Professor of Materia Medica and Botany in the Philadelphia College of Pharmacy. Henry C. Lea's Son & Co. Philadelphia. 1882. 450 pp.

The above manual, by a well-known authority in this department and one of the authors of the National Dispensary, is a work for which students of pharmacy should be grateful. The subject is one in which

the beginner needs the guidance of a good classification in order to avoid the bewilderment which follows the attempt to grasp a subject having so many details. This condition the book fulfills, the classification adopted being a simple and practical one; the notice of each drug is brief and clear, non-essentials being omitted.

It is fully illustrated by some two hundred woodcuts, and the work of the publishers has been well done.

*Lectures on Digestion.* An Introduction to the Clinical Study of Diseases of the Digestive Organs. Twelve Lectures Delivered to Practitioners and Advanced Students of Medicine during the Winter Session 1878-79. By DR. C. A. EWALD. Translated by ROBERT SAUNDCEY, M. D., Edin. New York: William Wood & Co. 1881.

Dr. C. A. Ewald is a lecturer in the University of Berlin, where this course was originally delivered, and was formerly Dr. Frerich's assistant at the Charité Hospital.

As the author tells us, in a short preface, his first consideration in this course has been for the interests of physicians and clinicians, and the arrangement and treatment of the subject-matter are from their point of view.

The translation is good, and its correctness was still further insured by a subjection of the proofs to the author's revision.

The twelve lectures make a 12mo of 150 pages, and should find appreciative readers.

*Winter and its Dangers.* one of Blakiston's American Health Primers, by DR. HAMILTON OSGOOD, has been published in a second edition in still cheaper form, with paper covers. It has evidently achieved considerable popularity.

— According to the *Lancet* a curious example of multiple biliary fistula has been communicated to the Medical Society of Cologne. The cystic duct was completely obliterated. The gall-bladder, in consequence, apparently, of the irritation of biliary calculi, had contracted adhesions to the duodenum, with which it communicated by a large fistulous opening. Near this was another opening by which the gall-bladder communicated with the colon. A third fistula existed between the duodenum and the colon. The common bile-duct was distended, and its cavity obliterated by two biliary concretions. These lesions were not suspected during life. The woman presented no jaundice, in spite of the closure of the ducts, on account of the free passage for the bile into the intestine. She had never suffered from hepatic colic. The chief symptom was constant diarrhea, which caused fatal exhaustion, in spite of a "canine appetite," which she strove unceasingly to satisfy.

— Dr. E. Adams, assistant medical superintendent of the Michigan Insane Asylum at Kalamazoo, was fatally stabbed by a patient who was thought harmless.

**THE HARVARD MEDICAL SCHOOL 1880-81.  
PLANS FOR THE FUTURE.**

THE report of the dean of the Harvard Medical School, Dr. Calvin Ellis, to the President of the University appears as usual in the annual report of the President and Treasurer of the University for the year 1880-1881, just published. From it we learn that the whole number of students in attendance during the year was two hundred and fifty-one; during the first term two hundred and forty-five; during the second two hundred and forty. Of these one hundred and twenty had a literary or scientific degree. There were eighty-five applicants for the degree of Doctor of Medicine, of whom twenty-five were rejected. Sixty passed the examination and received their degrees. As compared with the preceding college year this shows a falling off in attendance during the year of twelve; the number of those possessing a literary or scientific degree was one less; there were eleven more applicants for the degree of Doctor of Medicine, no names were withdrawn, and twenty-five were rejected, whereas in 1879-1880 ten applicants withdrew their names, and nineteen were rejected, forty-five degrees being then bestowed. The attendance in 1879-80 was slightly less than in the previous year.

The results of the preliminary examinations for admission to the school are given in a table, in regard to which, for purposes of comparison, it should be mentioned that since last year English and an elective have taken the places of French and German. Of the forty candidates examined four were rejected; of those receiving conditions the Latin proved too much for twelve, the physics for nine, their electives for six, while one unfortunate aspirant in June, and one again in September, failed to give satisfaction in English. The report saying nothing on the point, we may allow ourselves to hope that the two failures represent but one individual.

In regard to the fourth-year course the report says:—

"The results of the fourth-year course require separate mention. The class was composed of ten students, of whom five received hospital appointments, one took the ordinary degree of M. D., and four applied for the special degree intended for those who passed the examination of the fourth year, but as none of the four applicants fulfilled all the requirements this degree was not awarded. The small size of the class should cause neither surprise nor disappointment. At the time the change was announced the plans of

the young men in the school had already been formed, and their studies had been arranged with reference to graduation at the end of three years. Moreover, the opportunities for entering the various hospitals attracted a number of the best students.

"The results of this attempt to prolong the period of study cannot be determined for a number of years. If it is to succeed the value of the additional instruction must be so manifest as to induce those interested to avail themselves of it; the student must begin his studies with the idea of prolonging them, and must arrange them accordingly; and, as the hospitals must continue to demand their quota of assistants, these institutions must be satisfied that the services of young men who have studied four years are more valuable than those of students whose systematic instruction has terminated at the end of three. The attention paid to the second of these conditions already offers encouragement. In 1880-81 of sixty-nine matriculants fourteen, or twenty per cent., announced their intention to take the additional course; while in 1881-82 of seventy-nine matriculants twenty-four, or thirty per cent., announced a similar intention."

The experience of the year in this matter of a fourth-year course is merely a realization of the anticipations expressed when it was resolved upon; time must necessarily elapse before the actual results of the step become evident. It will probably prove merely the approach to something more decided.

Of those graduating in 1881, eight per cent. spent six terms at the Harvard Medical School, ten per cent. five terms, six per cent. four terms, and one per cent. three terms; these proportions not varying materially from those of the previous three years.

The receipts of the school from all sources—invested funds, instruction, and graduation fees, etc.—were \$57,464.07; the expenses were \$59,276.55.

A new building for the Harvard Medical School is, as many of our readers know, now in process of erection at the corner of Boylston and Exeter Streets, in the new part of Boston. Seven years ago a handsome sum of money was raised for this purpose, which in April, 1880, amounted, with accumulated interest, to \$173,325. At that time the site for the present new building was bought for \$83,325, leaving \$90,000 for the building funds. Messrs. Ware & Van Brunt, architects, were requested to prepare plans for the new building. In regard to these plans the President of the University reports:—

"A large committee of the Faculty was appointed to give advice as to the size and internal arrangement of the building, and the fittings which its peculiar destination would call for. The desire of the Corporation and the patient endeavor of the architects were to devise a building adapted in every respect, within and without, to its probable uses, so far as they could be foreseen; and the committee of the Faculty spared no pains in studying these uses, and devising the best means of providing for them with all practical convenience and completeness. As four fifths of the building were to be taken up by the laboratories and lecture-rooms, histology, chemistry, and surgery, the

requirements in regard to light, heat, and fresh air were unusually stringent, and the provision of flues, drains, and fittings for water, gas, and steam was elaborate and peculiar. It was further necessary that the exterior of the building should be not unsuitable to the handsome quarter of the city in which it was to be placed, and that throughout the structure every precaution should be taken against fire. Under these circumstances it was not surprising to find, when the plans and estimates were completed after six months' labor, that the cost of the building would not be less than \$190,000.

"In this state of things, the Medical Faculty, moved by the hopefulness of a few of their number, resolved that an effort should be made to raise another considerable sum by subscription, and in three weeks two members of the Faculty, almost unaided, procured the subscription of \$103,720. Work was begun upon the building early in June last, and it is hoped that the whole building will be ready for occupation by the first of January, 1883."

To complete this good work endowments for scholarships and professorships are now urgently required, or a large permanent fund the increase of which shall be applicable to salaries, and thus enable the University to secure for the school the elevated position as the disinterested guardian of sound medical learning which is so earnestly desired for it by its friends. In regard to this point we again refer to the report of the President, who is never more eloquent than when depicting the wants of the University under his charge. He says, and truly, that so long as medical schools are conducted as private ventures for the benefit of a few physicians and surgeons who have united to form a corporation or faculty, the community ought not to endow them; for it is contrary to the best interest of the public that medical education should be conducted in that way. The experience of the past hundred years in this country proves that such medical schools will not be endowed. While several millions of dollars are yearly devoted to education in arts and in theology by intelligent and public-spirited men and women, hardly anything is given for education in medicine, because almost all American medical schools are organized and carried on as commercial adventures. In 1871 the Harvard Medical School ceased to be in any sense a private venture, and became a constituent department of the University, devoted, like the other departments, to the advancement of science and learning, and to the amelioration of the conditions of human life. Since that year it has received by gift and bequest \$270,000; but this sum, though considerable, is not one third of the endowment which it urgently needs. The objects of endowment in medical education are precisely the same as in other departments of education, namely, to provide permanent means of securing the most competent persons for its professional chairs, of helping poor students of rare capacity, and of advancing knowledge by new researches. It is the primary object of medical science and art to defend and improve the life that now is,—the life of the individual, of the family, and of society; but since

it is impossible to separate physical from mental and moral well-being, the domain of medical science is really coextensive with human nature. Whatever motives induce benevolent persons to endow institutions which teach the humanities or theology should also avail for the endowment of medical education. The seed and the fruit, the planting and the harvesting, may be different in kind; but these various cultures all have in view a common end, namely, the improvement of man's estate.

In this same number of the JOURNAL will be found remarks from the pen of Dr. Oliver Wendell Holmes and extracts from an excellent editorial on the columns of the *Boston Daily Advertiser* upon the endowment of the School.

The establishment of the Harvard Medical School upon a thoroughly independent basis is by no means a matter of merely local interest or contributing only to the aggrandizement of a single university. No long time need elapse to make the attainment of these ideals felt in medical education, in medical science and practice throughout the country.

#### THE MASSACHUSETTS HEALTH REPORT.

THE second health supplement to the Report of the State Board of Health, Lunacy, and Charity of Massachusetts (for the year 1880) has appeared so late and so reduced in size that the friends of sanitary science begin to fear that the work of the State Board of Health has been so merged into other departments as to be in danger of losing its existence altogether. In the list of past and present members of the Board we already find six retired, while we know that several accomplished gentlemen have refused appointments to an office requiring such multifarious duties.

The subjects considered in the report are the pollution of streams, in continuance of previous investigations, intermittent fever in Massachusetts, the separate system of sewerage, school-house sanitation, an epidemic of diarrhoea in the town of Adams, the sanitary condition of Holyoke, and there are a dozen or more pages on the neglect of vaccination. In the general report of the Board there is also a brief report of the analysis of 103 samples of bread, of which 90 were entirely free from alum, the loaves selling for five cents, varying in weight from 229 grammes to 489 grammes, and in amount of moisture from 31.42 per cent. to 65.27 per cent.

In the basins of the two rivers examined by Mr. W. E. Hoyt, namely, the Miller and the Deerfield, there is shown to be some easily avoidable contamination from saw-mills, tanneries, gas works, and privies connected with manufactories, as well as some filth from cotton mills and woolen mills in a few places, all of which does no more harm than a certain amount of offense to the senses of sight and smell, as neither stream is used for drinking purposes, except that in Gardner some mill owners complain that the water is injured for their purposes by the drainage from privies

above them. A plan to utilize the sewage of Greenfield has been submitted, but in what way the reader is not informed further than that the experiment is to be allowed for a limited time at the expense of the gentlemen proposing it.

Mr. Eliot C. Clarke's treatment of the separate sewerage system is very timely, and he describes the advantages and disadvantages of the system in a way to materially assist the solution of the difficult drainage question, which is now presented to most towns that aspire to be much more than villages. The smallness of its first cost, as compared with the double system, and the rapidity with which it can be introduced, may make it of absolute necessity, as, for instance, in Memphis, where the danger and inconvenience from flooding the streets in time of storm may be comparatively slight. Where, however, as is the case in most large cities, a great amount of rain water must be removed from the streets, and it is desirable to drain the soil and deep cellars, the double system is likely to be the most serviceable, and in the end the cheapest. The separate system was first introduced in England in order to reduce the bulk of the sewage to the smallest quantity possible, for the purpose of irrigation on a small amount of land, the discharge into a neighboring stream having been forbidden by law. Where sewage must be pumped, the question of keeping the rain-fall separate must be an important element in the annual cost of the works; but it must be remembered that the grades required for the small sewers of the separate system must be sharper than for sewers conveying storm-water also. Both kinds of sewers require artificial flushing, and, with the same degree of skill in construction, both are about equally liable to deposits.

The epidemic of intermittent fever which for five successive autumns has prevailed in Massachusetts, was in the first three years of its gradual increase coincident with a decrease in the annual number of deaths from typhoid fever progressively from 814 to 637 or to 3.7 per 10,000 of the population, the lowest death-rate from that cause ever known in this State, as compared with 11.1 in 1872. In 1880 there was a rise to 4.9 in typhoid fever, and also a marked increase in the intermittent fever; while in 1881 there was probably an increase in typhoid fever, and a decline in intermittent fever, although the statistics are not yet available on that point. Where the two diseases prevail together, too, the reports of prevalence are certain to be somewhat in error, from confusion of the two diseases, and from placing to one or the other exclusively those cases in which there exist the pathological conditions characteristic of both diseases. In the investigation for the Board by Dr. J. F. A. Adams, of Pittsfield, the fact is mentioned that there was a prevalence of fever and ague probably during the early colonial period, and that it disappeared by reason of drainage to reappear in moderate epidemics from 1793 to 1799, and from 1828 to 1836, in scattered towns, chiefly in the river basins of the western part of the State. In 1870 there were a few cases in Springfield, and for the next six years quite a number of cases occurred, for a time thought by many physi-

cians to be a mild form of typhoid fever, chiefly in Berkshire County and the Connecticut Valley. There had been a general northward progress of the disease, starting from Long Island Sound in 1861. In the recent epidemic in our State, up to the winter of 1880, there were cases reported in fifteen towns on the Connecticut River, in six on the Housatonic, in three on the Hoosac, and in one each on the Ware, Nashua, Merrimac, Concord, Saugus, and Taunton. The conditions of prevalence have been low lands in river valleys, but sometimes higher localities near reservoirs, or ponds, or marshes, or bodies of stagnant water exposed to unusual or prolonged heat. It is reported that eight cases of intermittent fever had occurred on the high, sandy soil of Southwick, a fact so new in the history of that disease that one naturally, but in vain, looks for a thorough investigation or explanation of it. In the three years, 1878 to 1880, there were ninety cases on the Housatonic River, in forty-two houses, or more than two thirds of all the dwellings on the two sides of a shallow, ponded reservoir, about four miles long.

From Mr. Ernest W. Bowditch's report on school-house sanitation, it appears that some of the school-houses in our larger cities are in a condition to seriously endanger the health of the pupils, although the best are of a reasonably good standard. The improvements which may be made in nearly all, however, suggest the hope that either our State Board of Education or our State Board of Health, which we hope and expect to see revived, may take the matter in hand, and organize an efficient system of medical inspection for all the schools in the Commonwealth.

A curious epidemic of diarrhoea in the town of Adams is described by Dr. J. F. A. Adams, attacking 1112 persons out of the 4634 enumerated, the greatest prevalence having been among adults. Throwing out days in which there were only ten cases or less, the epidemic lasted five days. There were nine each ascertained to be on June 13th and 14th, 636 June 15th, 136 June 16th, 46 June 17th, 30 June 18th, 12 June 19th, 6 June 20th, 4 June 21st, and 10 June 22d. It lasted one day in nearly one half of the cases, two days in a quarter, three days in one eighth, and in only one twentieth over a week. By ages, 11.5 of the population under five were ill, 13.3 per cent. of those from five to ten, 25.7 per cent. from ten to fifteen, and 28.1 per cent. of adults. No deaths occurred. While the evidence pointed to the public water supply as the probable source of the trouble, its immediate cause was not ascertained.

The sanitary condition of Holyoke is illustrated by Mr. Bowditch's very ingenious, graphic method. Some excessive overcrowding and generally bad drainage are shown. The report closes with some remarks upon the neglect of vaccination by Dr. Z. B. Adams.

The report is no longer for sale at the State House. Physicians will be glad to learn that by recent law it is to be had upon application at the Document Room.

This is also the case with the last Report of Births, Marriages, and Deaths, which was printed in an enlarged edition to supply those physicians who desire

to study the vital statistics of the State from year to year. It is distributed at the State House upon application. Copies are no longer sold.

### MEDICAL NOTES.

—The King of Bavaria has requested Duke Dr. Carl Theodore to make himself thoroughly acquainted with the military hospitals of Munich, and the military medical service of all Bavaria, preparatory, as it is understood, to putting the duke at the head of the Military Medical Department of Bavaria. We shall welcome such an appointment with great satisfaction, for then for the first time will the highest post in military medicine of a country be in the hands of so influential a person as a member of the royal family must be. In such a post the duke may render inestimable service, and the action of his beneficial influence may be felt far beyond the boundaries of his own country. — *Wiener Med. Woch.*, November 26th.

—Statistics brought up to October 1st show that the inoculations of splenic fever, according to Pasteur's method, were performed on 160 flocks, comprising 68,900 sheep, of which 33,576 were vaccinated, and 21,938 animals were left uninoculated, so as to judge of the results of the difference of treatment. Before vaccination the losses caused by splenic fever amounted, on the whole of the flocks, to 2986 animals. During vaccination, and until its effects were perfected, 260 sheep out of the whole number of 33,596 perished. During the same period the mortality rose to 366 out of the group of 21,938 which were not vaccinated. When the effects of vaccination were complete in the first group the mortality from splenic fever fell to five. This rate has persisted up to the present time, and the next statistical account will give, it is expected, the same satisfactory results as regards the groups of animals vaccinated and left unvaccinated.

—The four volumes of the Transactions of the International Medical Congress have been published. The promptness of their appearance might well be imitated by other less bulky Transactions.

—It is acknowledged that one electric light in Boston has the same effect as five policemen "in uplifting the moral condition" of the people. — *Exchange*.

—Hospital Saturday and Sunday collections in New York have amounted this year, according to the latest statement, to \$30,902.42.

—MM. Cabitan and Charrin, of Paris, have been led by recent investigations to declare that in mumps, too, there lurks a specific infectious germ, — a micrococcus who has not yet been baptized.

### ST. LOUIS.

—At the annual meeting for the election of officers of the St. Louis Medical Society, which took place lately, the following gentlemen were elected for the ensuing year: president, Dr. William Dickinson; vice-president, Dr. Edward Borek; recording secretary, Dr. Oman-Dumesnil; corresponding secretary, Dr. G. F. Dudley; treasurer, Dr. W. E. Fischel.

### Miscellany.

#### ENDOWMENT OF THE HARVARD MEDICAL SCHOOL.

AMONG the branches of knowledge which are taught in schools not one comes so directly home to the needs of all communities and every condition of human beings as that which deals with the issues of life and death, of health and disease, as affecting the public and individuals. Sooner or later most persons must call upon medical art, for themselves or others, in one of those moments when the physician or surgeon is looked to as an earthly savior. But besides what he can do in saving life and in shortening the course of disease, it is impossible to estimate the amount of relief from suffering, bodily and mental, which is due to his ministrations. There is hardly any case so desperate that art cannot alleviate some of its symptoms, if it can do nothing more. And one thing the physician can always do: lift off that load of responsibility which falls upon the relatives and friends of a patient when they are least able to bear its weight. But we are looking forward to the time when much of the disease which now preys upon our city population shall be done away with, by the use of proper preventive measures. When the health of cities is properly cared for, they become green-houses, where the finest human fruit grows better than the average ill-protected out-of-door product. The study of the conditions which determine the healthfulness or sickness of centres of population and of different regions is to occupy a large space in the medicine of the future.

Medical science is only a special province of biology, the science which deals with the laws of life. It borrows much from other divisions of this great realm of knowledge. It levies contributions from other realms, from physics, from chemistry; it accepts a useful hint from whatever source it may come. A medical school has to teach much that seems incidental to medical practice, but only in this way can it send forth fully equipped practitioners. It begins with chemistry, anatomy, physiology, and thus prepares its students for study at the bedside and in the operating room. All this takes time and the cooperation of different experts, each of whom should be a master in his special department. There is a general tendency in this country to hurry through a student's medical education. Young men are impatient to be at work, and they will flock to a school which will give them a degree after a short period of study and a slight examination which they are almost certain they can pass successfully. In this way great multitudes of practitioners are sent forth not thoroughly fitted for their work, and the community has to suffer the consequences.

It is the province of Harvard University to set a higher standard in this most practical and vital branch of education, as it has already done in other less immediately essential departments of knowledge. This duty it has attempted to perform in the face of grave doubts and difficulties. In the performance of this duty it is now strenuously engaged. It has established a preliminary examination for admission into the school, thus excluding the ignorant and wholly untrained young men who would begin the arduous studies of a medical course without the knowledge and mental discipline which are necessary to fit them to profit by such instruction as is given in a medical school like that of our university. It has organized a regularly systematic and progressive course of instruction, in place of the mixed courses which have been long tolerated in spite of the general conviction and confession of their unphilosophical character and unsatisfactory impractical results. It has multiplied its courses of instruction so as to include the various important specialties which have developed of late years into separate professional branches. It has secured the cooperation of numerous clinical teachers in different public institutions, so that many of the advantages of the great foreign hospitals can be obtained without going abroad to find them. All this has not been done without the expenditure of much thought and labor, and without running a risk of financial failure which at one period was a source of anxiety, and the serious character of which is sufficiently illustrated by the course of one of the great medical schools of the commercial metropolis. The school referred to began the new system in which our own institution is now, as it had been for years, clearing the way for others, but found its resources so much diminished that it gave up the new plan and returned to its old methods.

A school which depends for its existence on the number of its students cannot be expected to commit suicide in order to satisfy an ideal demand for perfection. Any institution which is essentially dependent on the number of paying students it can draw must be tempted to sacrifice its higher aims to popularity. No high standard can be reached under such circumstances, and the

only way to ensure the independent action of a school which aims at teaching the whole country by example, is to endow its professors, so that the very best and highest grade of instruction, and not that which is popular because it is easy and superficial, may always be given from its chairs, whether the classes be large or small. A small number of thoroughly accomplished medical graduates, their knowledge based on sound scientific acquirements, and made practical by assiduous clinical observation and teaching, will be worth more to the country than twice or thrice the number of half-taught, hastily-taught, practitioners. A series of such classes will, in the course of a single generation, elevate the whole professional standard, as they go forth, year after year, missionaries in the cause of health, soldiers, if it need be, martyrs, in the unending battle with disease and its causes.

We bring this appeal before the community to be weighed with other claims, believing it to be one which will commend itself to all who wish to see our city established as the centre of educational intelligence, the normal school of the western continent. When we can offer the most complete medical education the New World has to give we shall have made one great step in that direction. The Old World motto is *noblesse oblige*. Our generous men of wealth are changing the phrase to *richesse oblige*, and thus becoming recognized as our untitled nobility. It is only necessary to show them in what way their beneficence will do the most extended and the most lasting good. The foundation of five or six professorships will carry the names of their founders down to a remote posterity and call them to honored remembrance when the stately buildings around us are replaced by other and still nobler structures.

O. W. H.

### THE HARVARD MEDICAL SCHOOL.

THE interesting statement which appears in another column of this impression, will be recognized as emanating from the eminent poet whose fame rests in good part on the services which he has rendered as a distinguished member of the Harvard Medical Faculty. Dr. Oliver Wendell Holmes submits some of the plans which the Harvard Medical School proposes to carry into effect if liberal and farsighted people will entrust to it on the ground of good policy a considerable fund for the benefit of this community, of this country, and of medical science. The school has been among the first and best in the country, but is unable to satisfy those demands which are justly made upon a medical school of the highest order. It is now making a praiseworthy effort toward raising the conditions on which students are admitted to the school; it attempts to establish a regular course of four years for all its students; it is building a new and more suitable home for the school, at the corner of Boylston and Exeter Streets; it hopes to retain its present home for clinical purposes; it desires to attract a larger number of students, and it wishes to reduce their expenses; it entertains the honorable and laudable ambition of being the foremost medical school of the country; and it proposes to make such further advance in the thoroughness and completeness of the instruction it can supply, that it will be no longer necessary for the medical graduate of the United States to continue and supplement his studies in foreign lands. All this can be accomplished by the endowment of professorships and by increasing the permanent fund of the school.

It would be wide of the mark to say that these facts are published for the sake of appealing to charity, the Harvard Medical School not being a charitable institution, but a professional establishment of honorable traditions and a great future. Its Faculty proposes to serve our time and the rising generation as its predecessors have served the past, and it has always been among the glories of the School that it has gone hand in hand with this community, with which it is so intimately allied. This community, which cannot be divorced from New England or the country at large, demands the best medical service which is to be had; and the Harvard Medical School is ready to supply the demand if its resources be increased so far as to accomplish two definite objects. It must be able to compete as to tuition with those medical schools which bestow the medical diploma after a study of two or three years, as well as exceedingly gentle examinations; and it must offer to the best talent among medical students all that is offered in the larger schools of Europe which are now attended by hundreds of American graduates. Both objects, it is safe to add, possess national importance, and cannot be wisely neglected.

The endowment of the Harvard Medical School now asked for is to be viewed, therefore, in the nature of a permanent investment. It is proposed that we shall do for the present and the future what the fathers have done so well for their time and for us. And there is special fitness in enlarging and strengthening

this particular School, which is already the first in rank of its kind in the country, and one of those establishments that have made Boston an intellectual centre honored throughout the United States. There is dignity and rich promise in adding to the intellectual resources of the New England metropolis. It will be worth all that it may cost if the Harvard Medical Faculty can be so strengthened as to solve those medical and sanitary problems which will make our city and other cities the happy home of the strongest men and the most healthful women in the land. "This may strike some readers as fanciful or imaginative, but it is true." It is no less true that we ought to have at least one medical school in the United States which may serve as a model to others, and will attract to Boston the hundreds of students who are now forced to finish their school education in foreign countries. Those who are interested in this endowment and who would have ample opportunity for putting \$500,000 to most excellent uses, are convinced that such an endowment would be a rational and profitable employment of wealth, an act of security and wise precaution, and withal the dictate of prudent foresight. — *Boston Advertiser*.

### SIXTY-SECOND ANNUAL MEETING OF THE WHITE MOUNTAIN MEDICAL SOCIETY.

THE White Mountain Medical Society held its sixty-second annual meeting at the Coosuck House, Wells River, Vt., January 4 and 5, 1882. A large number of members were present, and some very able papers were read. One was by Dr. Geo. S. Gove, of Whitefield, N. H., reporting a case of Cæsarean section, the first and only operation of the kind ever performed in New Hampshire.

Dr. Putnam, of Montpelier, Vt., read an interesting paper on diphtheria. The point made was the giving of large quantities of whiskey (in one case five pints in the first twenty-four hours) at the onset of the disease, with the idea of antidoting the poison, — as you would snake bites. He showed excellent results.

Dr. Q. A. Watson, secretary New Hampshire State Board of Health, gave a detailed account and the causes of the recent epidemic at the Orphans' Home on the Daniel Webster Farm, Franklin, N. H.

Dr. Mitchell, of Lancaster, N. H., read a report of a severe epidemic of puerperal fever occurring at Lancaster in May and June, 1881, also one of typhoid fever at Guildhall, Vt., and one at Lancaster in October, November, and December, 1881. In this last every one of the twenty-five cases drank water from a certain wooden aqueduct which was very rotten, the water at the same time being very low, and tasting badly.

Dr. Gibson, of Woodsville, N. H., read an instructive paper on the management of acute inflammatory affections of the ear in children during an attack of constitutional disease, as the exanthemata.

There were other valuable papers and discussions.

The New Hampshire State Society will print the most valuable papers with their own proceedings.

Officers elected for the ensuing year: president, Dr. O. L. Watson, West Topsham, Vt.; vice-president, Dr. E. Mitchell, Jr., Lancaster, N. H.; secretary, Dr. C. R. Gibson, Woodsville, N. H.; directors, Drs. C. H. Boynton, Ira Brown, and W. B. Moody; censors, Drs. C. M. Tuttle, Q. A. Watson, J. D. Folsom, Geo. S. Gove, G. B. Bullard, D. B. Smith.

### A CASE OF SUDDEN SWELLING OF FACE AND NASAL MEMBRANE.

MR. EDITOR, — The following case may be of interest in connection with the paper by the late Dr. T. B. Curtis, published in the JOURNAL some years ago,<sup>1</sup> on sudden and transient swellings of the lips. It differs

<sup>1</sup> Vol. cii., pp. 445 and 556.

from the cases there mentioned only in the situation of the swelling.

The patient is a young lady in good circumstances. She has always enjoyed good health with the exception of slight attacks of "hay cold" in the last two or three years.

On the afternoon of October 23, 1881, at about four o'clock, after being perfectly well all day, she suddenly felt a "choking sensation" and was unable to breathe freely through the nose. The obstruction increased rapidly, and in a few moments both nasal passages were completely closed.

She was seen an hour after the beginning of the attack. At that time the nasal passages were occluded, so that air could not be forced through them. The face was swollen and hard from one temple to the other, and from just above the eyebrows downwards to half way across the nose. The eyelids, especially the upper, were so swollen as to cause almost complete exclusion of light. Rhinoscopic examination showed the mucous membrane of the nares to be much swollen, but no foreign body could be or was subsequently discovered. The swelling of the face was hard, not painful nor red, nor was there any pitting on pressure. The pulse and temperature were normal.

In the course of another hour the swelling of the face began to subside, and had almost completely disappeared in four hours from the beginning of the attack. The next morning all traces of it had disappeared. The treatment was purely expectant and reassuring. A mild spray of tannic acid and glycerine was ordered, but recovery was so rapid that its effect could not have been great.

There was a slight laryngitis which had existed for some time, but yielded readily to treatment. Up to the time of writing there has been no sign of a repetition of the attack. Very truly yours,

HAROLD C. ERNST.

JAMATCA PLAIN, January 11, 1882.

### INSANITY AS A CAUSE FOR DIVORCE.

In the London Divorce Court on Friday, December 16th, according to the *Lancet*, a very important case was settled in reference to insanity. The case was *Hunter v. Edney*. In this case a woman was married, but refused on the wedding night to allow the marriage to be consummated. The husband sent for the mother of the woman, who took her home after she had been seen by Dr. Miskin, a general practitioner in the neighborhood. Dr. Miskin was of the opinion that then she was insane. Some few weeks later Dr. Savage of Bethlem saw the case, and decided that the woman was suffering from melancholia, and not fit to enter into a contract, and that in his opinion she had so suffered for some time. The whole case took but a short part of one day, and there was really no opposition, for though the wife was in court, and elected to go into the witness-box, she did not deny any of the statements made, but said that she had no knowledge of some of the things which were proved to have taken place during the time soon following her wedding. Thus, she did not remember, so she said, making an attempt to strangle herself. The judge, Sir J. Hannen, summed up clearly and fairly, and pointed out that the woman did not appear capable of understanding actions free from the influence of delusions, and was

therefore incapable of entering into a contract like that of marriage, and he decreed the marriage null. This is the first case of the kind which has been decided, and is not by any means a solitary one, so far as the insanity and marriage are concerned. During the past year several cases have, we believe, occurred in Bethlem in which marriage was not consummated in consequence of insanity. In one a man heard a voice telling him he must not touch his wife, and the same patient, later, heard a voice telling him not to eat. The case decided is a first one, and is incomplete. What line would have been followed if the marriage had been consummated, and still more, if a child had been begotten? The inability to contract would have been the same, but we fear there might have been greater difficulty to persuade a jury—if a jury had been deciding—that a divorce was justifiable. In murder cases the feeling of many is moved against taking human life, but the life-long misery caused by an unjust marriage in which one of the contracting parties was insane, is a suffering of the innocent which is unhappily overlooked. Such cases make it all important that something should be done, and every step such as the one reached in the above decision carefully watched.

### DEAFNESS AMONG LOCOMOTIVE ENGINEERS.

ACCORDING to Moos, the drivers and stokers of railway engines suffer, sooner or later, from diminished acuteness of hearing, due to the influence of their occupation. The deafness is usually bilateral, and some of the facts ascertained seemed to show that it comes on sooner in the men employed on railways in which there are many tunnels than in those who drive engines in level country. Moos suggested that this acquired deafness was a source of even greater danger than the color blindness, since it comes on gradually in those who are already engaged in the occupation, and the subjects are often unaware of the onset until by some accident, as exposure to severe cold or injury, it is suddenly increased. He left undetermined its comparative frequency, but the question has lately been reinvestigated by Schwabach and Pollonow, who have arrived at conclusions which confirm those of Moos as regards the facts, but are more reassuring as regards the danger to the public. They find that the work of the engine drivers and stokers almost invariably entails, after a time, diminution in the acuteness of hearing. Examining a larger number of these workmen it was found that the percentage in which deafness was to be detected steadily increased with each year of service, and the absolute number was considerable. Of 160 examined, no less than 33, or 20 per cent., were found to be more or less deaf. Of those who had only been employed a few years, the number with defective hearing was insignificant. The duration of service in 59 did not exceed five years, and of these only 5 (8.4 per cent.) were somewhat deaf. Among those who had been longer employed, not only was the percentage of deafness larger, but the degree was more considerable. Of 68 men who had been at the work from six to fifteen years, 14, or 20.5 per cent. were partially deaf; of 28 who had been employed for from fifteen to twenty-five years, deafness was found in 10, or 35.7 per cent.; while of 5 who had been at the work more than twenty-five years, in only one was hearing natural, the percentage of defect thus amounting to 80 per cent. In most cases a distinctly morbid condition of the mem-

brana tympani could be observed, which indicated a selective form of chronic catarrh of the middle ear. In only three cases was there evidence of a direct affection of the labyrinth. In spite of the demonstrable defect in hearing, most of the individuals asserted that it constituted no impediment in the performance of their duties, and this was rendered probable by the fact that the defect was chiefly recognizable by the tick of the watch, and that a whisper could be heard at a tolerable distance, and the shrill note of the guard's whistle was heard perfectly at the distance of a platform's length. These facts led to considerable skepticism regarding the public danger apprehended by Moos. To obtain more conclusive evidence on this important point some tests were applied during a journey. It was found that the whistle signal and detonating fog signal were heard perfectly well by persons whose acuteness of hearing for fine sounds was reduced to  $\frac{2}{3}$  or  $\frac{1}{2}$  of the normal, and for a whisper to  $\frac{3}{4}$  of the normal. It was found, also, that whilst the engine was in motion neither the guard's whistle nor a noise behind the engine could be perceived by a person whose hearing was perfectly normal. Hence the conclusion is reached that the deafness which arises in engine-drivers from their occupation is of no great consequence, and that as long as a conversation in an ordinary voice can be heard their defect involves no danger to the public.

Some hesitation may be reasonably felt in accepting this conclusion. Surely the engine-driver is often dependent upon his ear for other information than that derived from a fog signal or a starting whistle. Often an unwonted sound from some part of the engine is the first intimation that something has gone wrong with the machinery, the early recognition of which might be of importance. The signal by which passengers can communicate with the engine-driver appeals to the ear, and a slight signal amid the noise of the train might be unnoticed by men with a slight defect of hearing, although capable of being perceived in the normal condition of this faculty. So, again, in such an instance as the Canonbury accident, in which the signal man states that he gave a word of caution to the passing driver which the latter asserts he did not hear—whether such warning was or was not heard, or its exact purport recognized, might readily depend, in some instances, on the acuteness of the sense of hearing in the driver. Railway systems are so complex and delicate in their organization that those who work them need to have every sense in perfect operation. Pains have been taken to obviate the danger arising from color-blindness, and it is certainly desirable that investigations should be made to ascertain how far the effects on the hearing of engine-drivers observed in Germany are produced also in this country. — *Lancet*.

## REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 7, 1882.

| Cities.                           | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |                      |

## OBITUARY.

DR. WM. C. H. NEEDHAM, of Gallipolis, Ohio, who died at Columbus, last week, of pneumonia, was born in Groton, Mass., in 1845, graduated at Norwich Military Academy, Vermont, and took his medical degree at the Medical Department of Harvard University. He enlisted, and served his time as a volunteer in a Massachusetts regiment, in the war of the Rebellion, leaving his studies when scarcely eighteen years of age for that purpose. In 1878 he was city physician of Gallipolis, and at the time of his death was a member of the Ohio senate. He was deservedly held in high esteem in his adopted State, and was in every respect a most estimable gentleman. He leaves a widow and two children, and was the son of Hon. Daniel Needham, National Bank Examiner of Massachusetts.

## OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 31, 1881, TO JANUARY 6, 1882.

GORGAS, WILLIAM C., first lieutenant and assistant surgeon. The leave of absence granted him by paragraph 5, S. O. 150, headquarters, Department of Texas, December 3, 1881, is extended one month. S. O. 1, Military Division of the Missouri, January 4, 1882.

MADDOX, THOMAS J. C., first lieutenant and assistant surgeon. Now awaiting orders in Washington, D. C., to report in person to commanding general, Department of Texas, for assignment to duty. S. O. 2, A. G. O., C. S.

GYNACOLOGICAL SOCIETY OF BOSTON.—The next regular meeting will be held at the Medical Library Rooms, on the first Thursday of February, at eleven o'clock A. M. A. P. Clarke M. D., will read a paper on Removal of Intra-Uterine Fibroids. Profession invited. HENRY M. FIELD, M. D., Secretary.

THE SECTION FOR CLINICAL MEDICINE AND PATHOLOGY OF THE SUFFOLK DISTRICT MEDICAL SOCIETY will meet at No. 19 Boylston Place, on Saturday, January 21st, at 7.45 o'clock. Papers: Dr. G. H. Lyman, Some of the Sequelae of Typhoid Fever. Dr. Henry J. Bigelow, A Case of Disease of the Liver. Dr. F. C. Shattuck, A Case of Unintentional Aspiration of the Liver. Dr. Thomas Dwight, Frozen Sections of Pleuritic Effusion.

ALBERT N. BLODGETT, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED.—Frozen Sections of a Child. By Thomas Dwight, M. D., Instructor in Topographical Anatomy in Harvard University. Fifteen Drawings from Nature. By H. P. Quiney, M. D. New York: William Wood & Co. 1881.

Lectures on Electricity (Dynamic and Franklynic) in its Relations to Medicine and Surgery. By A. D. Rockwell, M. D. New York: William Wood & Co. 1881.

Handbook of Physiology. By W. Morratt Baker, F. R. C. S., Lecturer on Physiology, etc., to St. Bartholomew's Hospital. Tenth Edition, with one hundred and twenty illustrations. Philadelphia: Presley Blakiston. 1881.

Wood's Library of Standard Medical Authors. A Handbook of Uterine Therapeutics and of Diseases of Women. By Edward John Tilt, M. D. Fourth Edition. New York: William Wood & Co. 1881.

Transactions of the Michigan State Medical Society for the Year 1881. No. 1. Vol. VIII.

Sensation and Pain. By Charles Fayette Taylor, M. D. A Lecture delivered before the New York Academy of Sciences, March 21, 1881, being one of the Public Course for 1880-81. New York: G. P. Putnam's Sons. 1881.

Epilepsy and other Chronic Convulsive Diseases; their Causes, Symptoms, and Treatment. By W. R. Gowers, M. D., F. R. C. P. London: J. & A. Churchill. 1881.

Sir Thomas Browne's Religio-Medici Letter to a Friend, etc., and Christian Morals. Edited by W. A. Greenhill, M. D. Oxon. London: Macmillan & Co. 1881.

A Guide to Shipmasters visiting the Cape Fear and other Rivers. Presented by the North Carolina Board of Health.

## THIRTY-TWO CONSECUTIVE OVARIOTOMIES DURING THE YEAR 1881. BY JOHN HOMANS, M. D.

| No. | Date.           | Place of Operation.      | Condition. | Age. | Length of Incision. | Adhesions.                                      | Treatment of Pedicle.                                 | Weight of Tumor. | Result.   | Remarks.   |
|-----|-----------------|--------------------------|------------|------|---------------------|---|---|------------------|-----------|--|
| 1   | Jan. 6, 1881.   | Carney Hospital.         | S.         | 26   | 5 in.               | None.   | Tied and burnt off with Pagenstecher's thermocautery. | 11 lbs.          | Recovery. |  |
| 2   | Jan. 26, 1881.  | Carney Hospital.         | S.         | 38   | 5 in.               | None.   | Do.   | 17½ lbs.         | Recovery. | Dermoid cyst. Considerable ascites.  |
| 3   | Jan. 27, 1881.  | Carney Hospital.         | W.         | 63   | 5 in.               | To both Fallopian tubes and to sigmoid flexure. | Do.   | 9½ lbs.          | Recovery. |  |
| 4   | April 5, 1881.  | Carney Hospital.         | S.         | 40   | 6 in.               | None.   | Do.   | 5 lbs.           | Recovery. | Dermoid cyst, and attached to this a spindle-celled sarcomatous tumor. A uterine fibroid, two pounds' weight, also removed.  |
| 5   | April 14, 1881. | Carney Hospital.         | M.         | 40   | 4½ in.              | None.   | Do.   | 36 lbs.          | Recovery. | Died of exhaustion on the third day. Very severe operation. Tumor very vascular and nearly solid.  |
| 6   | April 16, 1881. | Carney Hospital.         | M.         | 42   | 8 in.               | Parietal, intestinal, and omentum.              | Do.   | -                | Died.     | Both ovaries removed.  |
| 7   | April 17, 1881. | Carney Hospital.         | M.         | 29   | 4½ in.              | Strong and old; anteriorly.                     | Do.   | 42½ lbs.         | Recovery. |  |
| 8   | May 5, 1881.    | Carney Hospital.         | M.         | 34   | 4 in.               | None.   | Do.   | 26 lbs.          | Recovery. | Much ascitic fluid.  |
| 9   | May 22, 1881.   | Free Hospital for Women. | M.         | 39   | 5 in.               | None.   | Do.   | 12 lbs.          | Recovery. |  |
| 10  | May 26, 1881.   | Carney Hospital.         | M.         | 42   | 7 in.               | Very vascular; anteriorly and to omentum.       | Do.   | 15 lbs.          | Recovery. | Considerable hæmorrhage during operation.  |
| 11  | June 8, 1881.   | Carney Hospital.         | M.         | 40   | 4½ in.              | None.   | Do.   | 10 lbs.          | Recovery. | Cyst dark blue, very vascular. In appearance resembling the fetal side of a placenta.  |
| 12  | June 9, 1881.   | Boston.                  | M.         | 42   | 4 in.               | None.   | Do.   | 13 lbs.          | Recovery. |  |
| 13  | June 11, 1881.  | Carney Hospital.         | M.         | 51   | 4 in.               | None.   | Do.   | 34½ lbs.         | Recovery. |  |
| 14  | June 21, 1881.  | Boston.                  | S.         | 18   | 4 in.               | Anteriorly and to omentum.                      | Do.   | 25 lbs.          | Recovery. |  |
| 15  | June 30, 1881.  | Carney Hospital.         | W.         | 55   | 6 in.               | None.   | Do.   | 13 lbs.          | Recovery. | Tumor cancerous.   |
| 16  | July 7, 1881.   | Carney Hospital.         | S.         | 39   | 5 in.               | None.   | Do.   | 8 lbs.           | Recovery. | Pedicle slipped from clamp before it was burnt off, and in order to pick it up and secure it the incision had to be enlarged. Cyst of broad ligament.  |
| 17  | July 11, 1881.  | Carney Hospital.         | S.         | 23   | 4 in.               | None.   | Do.   | 11½ lbs.         | Recovery. |  |
| 18  | July 25, 1881.  | Carney Hospital.         | S.         | 14   | 3 in.               | None.   | Do.   | 11½ lbs.         | Recovery. | Both ovaries removed.  |
| 19  | Sept. 7, 1881.  | Boston.                  | S.         | 49   | 3 in.               | None.   | Do.   | 12 lbs.          | Recovery. | Cyst of the left broad ligament.   |
| 20  | Sept. 1, 1881.  | Carney Hospital.         | S.         | 24   | 3 in.               | None.   | Do.   | 2½ lbs.          | Recovery. |  |
| 21  | Sept. 8, 1881.  | Carney Hospital.         | S.         | 25   | 7 in.               | None.   | Do.   | 13 lbs.          | Died.     | Cause of death, acute oemia on eighth day. A careful autopsy, by Dr. W. W. Gammett, showed everything healthy and going on well in the peritoneal cavity. Hereditary insanity in the family. Dermoid cyst. |
| 22  | Sept. 11, 1881. | Carney Hospital.         | M.         | 41   | 5 in.               | Anteriorly to plicates and to uterus.           | Do.   | 33 lbs.          | Recovery. |  |
| 23  | Sept. 18, 1881. | Carney Hospital.         | W.         | 51   | 3½ in.              | Anteriorly to plicates.                         | Do.   | 33 lbs.          | Recovery. |  |
| 24  | Sept. 27, 1881. | Taunton, Mass.           | M.         | 60   | 5 in.               | None.   | Do.   | 10 lbs.          | Recovery. | Some ascites.  |
| 25  | Oct. 4, 1881.   | Boston.                  | M.         | 45   | 7 in.               | Universal anteriorly and laterally.             | Do.   | 8-90 lbs.        | Recovery. | Considerable ascites, which is coated to the weight.   |
| 26  | Oct. 5, 1881.   | Boston.                  | W.         | 45   | 6 in.               | None.   | Do.   | 22 lbs.          | Recovery. | Both walls of bladder incised. No ill effects.   |
| 27  | Oct. 24, 1881.  | Merrimac, Mass.          | S.         | 57   | 6 in.               | Intestinal.                                     | Do.   | 5½ lbs.          | Recovery. | A portion of sac adherent to bowels left behind.   |
| 28  | Oct. 29, 1881.  | Boston.                  | M.         | 48   | 4 in.               | Slight lateral and anterior.                    | Do.   | 49 lbs.          | Recovery. |  |
| 29  | Nov. 15, 1881.  | Boston.                  | W.         | 47   | 3½ in.              | None.   | Do.   | 25½ lbs.         | Recovery. |  |
| 30  | Nov. 19, 1881.  | Concord, N. H.           | W.         | 73   | 6 in.               | To peritonæum, omentum, and intestine.          | Do.   | 20 lbs.          | Recovery. | The age of the patient did not prevent a very rapid recovery, 99.4° F. being the highest temperature.  |
| 31  | Dec. 1, 1881.   | Provincetown, Mass.      | M.         | 52   | 6 in.               | Burst cyst.                                     | Do.   | 35 lbs.          | Recovery. | Abdomen filled with gelatinous material, — colloid, — which had originally come from a burst dermoid cyst.   |
| 32  | Dec. 18, 1881.  | Free Hospital for Women. | S.         | 39   | 7 in.               | To intestine and pelvic peritonæum.             | Do.   | 10 lbs.          | Died.     | Both ovaries removed. The outer surfaces of the tumors of a brown color, and beginning to decay.   |

The above list contains all the cases of complete ovariectomy that I operated on during the year 1881. Besides these completed cases I have made three exploratory incisions, and closed the wound after thoroughly investigating the tumor. All of these cases recovered. So that we have for completed and attempted ovariectomies thirty-five cases, with three deaths. I have also operated for the removal of uterine tumors three times. Once successfully (Case 4 of this table) and twice with a fatal result, both of the latter being incomplete operations. One of the deaths in this table (No. 21) ought not to be accounted a death from ovariectomy, for everything in the abdominal cavity was going on well, as shown by autopsy. The pa-

tient's parents and family were more or less insane, and she developed acute mania, with the delusion that she had committed the unpardonable sin, and that there was no forgiveness for her. It would be improper not to report the case, however, and so I have called it a death from ovariectomy. Clinically, the wounding of the bladder in No. 26, without the least unfavorable consequences or the slightest retardation of convalescence, and the age of No. 30 (seventy-three years), with a normal and rapid recovery, are worth noting. I have also done colotomy successfully, making the permanent opening in the pubic region.

# CONDITION AND CIRCUMSTANCES WHICH SHOULD INDUCE THE MEDICAL EXAMINER TO EMPLOY A CHEMIST.<sup>1</sup>

BY E. P. MILLER, M. D., OF FITCHBURG.

THE subject which I have chosen does not permit any original investigation or experiment, nor does it even allow a presentation and discussion of the opinions of authorities, for I have been entirely unable to find anything in books bearing directly upon this question. I shall only attempt, therefore, to call attention to the importance of the subject and to give my own idea of the proper method of proceeding in order to decide correctly, as individual cases arise, the question whether or not to employ a chemist. For it is manifestly impossible to create a set of rules by mechanically following which the medical examiner can be sure of a correct decision. No two cases of suspected poisoning are exactly alike in history, symptoms, and pathology. After all is said, nothing will be found as a substitute for the medical examiner's own judgment and discretion.

Somewhat over a year ago I was placed in what I felt to be a very difficult and embarrassing position. A lady well known in a small city had died under circumstances which suggested poisoning, and I had decided to make an autopsy. The illness had been short, but the symptoms gave no clew as to what poison, if any, had been administered. The main reason for investigating the case was the fact that, from the history, no satisfactory diagnosis could be made, while it was known, also, that two other deaths had occurred in the same family within a short time. Nobody was ready to believe that the lady would destroy herself, nor had any one been about her who seemed capable of doing her any harm. There seemed, however, to be sufficient mystery about the case to demand an autopsy, and I decided to perform it. By the most careful inquiry I could form no opinion in advance as to what pathological appearances I might find, and not having the confidence which years of varied experience must give, I approached the work with considerable hesitation and anxiety. I was afraid, on the one hand, that the death was due to natural causes, the evidence of which might escape me; on the other, I was anxious not to return as a natural death one really due to poison, and so, perhaps, permit the escape of a criminal. At the autopsy no sign of disease could be found, but there was unmistakable evidence of poisoning, and the chemical analysis discovered a large amount of arsenic. The cause of death was thus made plain; and, fortunately for my peace of mind, I had done the proper thing in employing a chemist. A careful man will, and I think all should, always undertake the autopsy in such cases with a certain amount of fear. His mind should be perfectly unbiassed; he should not be determined in advance whether to find evidence of poison or of natural death. The one thought should be to find everything pathological about the body, whether it points to disease or to poisoning, as when a case comes to trial it is found by the medical examiner that every sign of disease becomes of the greatest importance, and that he must be prepared to testify, not only that the death could have resulted from poison, but also that it could not have resulted from disease. To be sure, this is exactly the work for which the medical examiner is supposed to be qualified and prepared.

<sup>1</sup> Read before the Massachusetts Medico-Legal Society.

Yet when we consider the results which may follow a mistake in either direction we must agree that the decision to employ, or not to employ, a chemist should be reached only after the most careful consideration of all the evidence in the case. It may be said that the whole matter is very simple, and that we should employ a chemist whenever we cannot satisfy ourselves, by an autopsy, of the cause of death. While this may be true to a certain extent, yet there are reasons for not employing a chemist unnecessarily. For instance, the mere fact that a chemist is employed may cause irreparable damage to the reputation of an innocent person. In the case above alluded to, in spite of great precaution, it became known that a chemist had been consulted, and suspicion immediately fastened upon a relative of the deceased who had previously borne a good character. Again, in one county at least, the commissioners constitute themselves the judges of all a medical examiner's acts; they reserve to themselves the right to pay bills or not, according as they think them necessarily contracted. From the mistake of not consulting a chemist when poison has been given the very serious result might be the escape of a murderer. But the whole reason for the existence of the medical examiner is the protection of society by detecting crime. When a poisoning case has once come into the hands of the law the chance that the medical examiner may not consider the evidence sufficient to warrant a chemical analysis affords the criminal his first loophole for escape. If murderers are to go free it should be through the lawyers rather than through medical men.

Perhaps of secondary importance is any loss of professional reputation which the medical examiner may suffer. This would certainly follow a wrong decision if, by any chance, his mistake should be discovered subsequently, or if at the time he could not satisfy the public mind.

In connection with the escape of criminals through an oversight of the medical examiner, I should like to remark that a very interesting question for speculation is whether it is possible that murders are being committed about us and remaining undetected or even unsuspected. From its very nature the question cannot be answered positively. Whatever may be true of the past the number of such murders ought certainly to diminish each year in civilized communities. According to the opinion of Taylor, expressed in 1873, such murders are (or were) very possible in England under the coroner system. For he says that in his opinion that system "affords no certainty for the detection of crime; it affords no protection to those who are wrongly charged with crime; and, lastly, it in some cases screens a criminal by a verdict based upon an imperfect inquiry, in which the important medical facts are either not understood or are misinterpreted by the jury." The number of exhumations suggests the possibility of secret murder. Taylor says, again, that in thirty years' practice, fifteen cases of exhumation were referred to him in which the death was proved to have resulted from poison. In some of the cases an inquest had been held. I have in mind a case occurring in this State in which a body was exhumed after fourteen years and arsenic found. We trust that the medical examiner system is better calculated to detect crime than its predecessor, yet it seems possible that there are murders unsuspected even by the friends and attendants of the deceased, which, of course, do not

come into the hands of the medical examiner at all. If acute poisoning is usually detected, may it not be true that chronic poisoning frequently is not?

These considerations may convey some idea of the importance of our subject. The investigation of a case of suspected poisoning seems to me the most delicate and difficult work the medical examiner is called upon to do. Not the least difficult of the many questions arising is whether or not to employ a chemist. The law under which we work affords little help, as it simply says: "The medical examiner may, if he deems it necessary, call a chemist to aid in the examination of the body or of substances supposed to have caused or contributed to the death." The evidence to be used in deciding this question of necessity may be discussed under two heads, as it comes from two entirely different sources:—

(1.) Evidence from the history of the case, including symptoms, and (2) evidence derived from the autopsy.

Evidence of either class may alone be sufficient to decide the question. Thus, in the first place, it is sometimes proper to decide before beginning the autopsy that a chemist should be employed. The cases in which, for the purpose of having a chemical examination, a body is exhumed, perhaps years after death, when the post-mortem appearances can have no diagnostic value, suggest themselves at once as examples. The autopsy in the case above alluded to was immediately followed by two others. Within the three weeks previous to the death of this lady her father and mother had both died after short illnesses. No positive diagnosis had been made by the attending physician, and there had been in each case some symptoms which might be attributed to a poison. Consequently the bodies were disinterred, and though a careful autopsy was made in each case I had previously determined to have a chemical analysis, whatever the autopsies might disclose. This decision seemed justifiable under all the circumstances and considering the unanimity of public opinion. For, on the discovery of arsenic in the body of the daughter, the public mind decided at once that the father and mother must have been poisoned also. At least, there was a universal demand for an investigation. Here it seems proper to say a word concerning this public sentiment, as the medical examiner may at times very plainly feel its force. Perhaps the chances are that in any given case the opinions of the public and those of the medical examiner will agree. When they do not I think great respect should be given to public opinion, and that the medical examiner may be influenced somewhat by it, unless he is absolutely sure of the ground on which he stands, and unless individuals are going to suffer manifest and great injustice. At all events it is easy to imagine a very disagreeable state of affairs, and one especially uncomfortable for the medical examiner, when he sees his duty clearly in one direction and the public or a neighborhood thinks it sees it in another. Such cases require the greatest tact and judgment in their management, as the medical examiner, and even the law itself, may fall into disrepute.

Sometimes it is possible to base a decision to have an analysis on symptoms alone, regardless of the pathology and the moral history of the case. Christison contends that no disease can successfully mimic the effects to which strychnia and hydrocyanic acid give rise. Taylor once concluded from the symptoms that

strychnia had been given, though he had failed to find it. If symptoms are ever proof of the presence of poison they must still oftener be characteristic enough to demand an analysis. The conditions found in some cases of poisoning by strong irritants—the state of the lips and mouth, impending suffocation, coldness of surface, acid stains on bedclothes—should lead to a thorough analysis.

Thus we see the nature of the evidence from which the medical examiner may determine to employ a chemist before the autopsy. Just what and how many suspicious acts on the part of persons accused, just what symptoms and how characteristic, just how strong and plainly expressed a public demand are necessary, it is impossible to state in advance. This is where the skill and discretion of the medical examiner are displayed, and each case must be treated as it arises.

We now come to a consideration of the autopsy, and, for the moment, may suppose ourselves dealing with a body of whose history nothing is known. What conditions as found post mortem should lead to the employment of a chemist? A complete discussion of this question would involve a statement of the pathology of all poisons and a comparison with the pathology of all diseases, which would involve many long details of which every medical examiner is supposed to have obtained sufficient knowledge in the course of ordinary study and practice. I shall, therefore, offer only a few general considerations, and mention some appearances which should lead to an analysis regardless of the history.

Poisons may be divided into two great classes, irritant and neurotic. On a general survey of the post-mortem lesions as detailed by authorities one is struck by the frequent absence of characteristic effects. The whole class of neurotic poisons as a rule do not leave any well-marked appearances in the body, and this class includes such well-known poisons as opium, strychnia, belladonna, aconite, and digitalis. Both irritants and neurotics may destroy life without leaving any appreciable changes in the body. "Evidence derived from post-mortem appearances can merely be more or less suggestive. Only a few poisonous substances make such decided impressions upon the living tissues as to warrant even a very strong presumption of their presence."<sup>1</sup> In case of all neurotic poisons it seems safe to say that we cannot expect to find at the autopsy sufficient positive evidence to warrant even a decision as to the necessity of a chemical analysis, to say nothing of finding a cause of death. Here should be expected, however, autopsies where the odor of such poisons as alcohol, chloroform, and hydrocyanic acid can unmistakably be detected; these odors are sufficient to call for an analysis, even if they are not positive proof of the presence of the poison. But the absence of the odor is no proof of the absence of the poison.

Irritant poisons are more likely to leave post-mortem signs, and the lesions in some cases are more characteristic. "They act chiefly on the stomach and intestines, which they irritate, inflame, and corrode. We may likewise meet with all the consequences of inflammation, such as redness, softening, thickening, ulceration, and perforation."<sup>2</sup> But each of these conditions may depend upon disease as well as upon the action of irritant poisons. There are various points of difference between these appearances when produced by dis-

<sup>1</sup> Reese on Poisons.

<sup>2</sup> Taylor's Manual of Medical Jurisprudence.

ease and similar appearances produced by poisons, yet it may be very difficult, if not impossible, to make the distinction without knowing the history of the case. I should consider any of these lesions, much more a combination of them, sufficient to demand an analysis, unless poisoning could be eliminated in some other way. As neurotic poisons may leave their odor, so irritants may cause very characteristic signs of their presence (not true pathological lesions), any of which should call for an analysis. Such are the white patches of arsenious acid sometimes found firmly attached to the mucous coat of the stomach, the peculiar slate-colored deposit said to have been seen in the stomach after poisoning by corrosive sublimate, and the remains of poisons themselves sometimes discovered by close inspection. Here, too, may be noted the preservative effect of arsenic.

This attempt to consider the nature and weight of the evidence furnished separately by the history, symptoms, and autopsy, may at least have suggested the importance in every medico-legal case of gaining evidence from every possible source. The history, or the autopsy, taken separately, is often entirely inconclusive, while the two together may be decisive.

Poisoning has been suspected in cases of death from various natural causes; for instance, peritonitis, intussusception, strangulated hernia, and more rarely rupture of the stomach or duodenum, rupture of the bile ducts, and rupture of the uterus. By combining the history and the autopsy in such cases it is often possible to declare that death could not have been caused by poison. The evidence from the autopsy can always be obtained unless decomposition prevents, while an exact and reliable history may easily be wanting. To be deprived of either class of evidence can only be considered a misfortune. Yet if all the obtainable evidence is duly weighed, if our reasoning is founded on facts and not on theory, we may expect to decide the question under consideration to the advantage both of the public and of ourselves in the vast majority of cases.

I trust that the somewhat desultory and unscientific character of this paper may be attributed partly to the nature of its subject, which hardly seems to admit a more precise and definite answer.

### NORMAL CEREBRATION FOLLOWING THREE YEARS OF DISEASED MENTAL ACTION; THE MYSTERY OF ITS PATHOLOGY.

BY C. F. RANCOFT, M. D., BOSTON.

AMONG the insane the physician occasionally sees a chronic case, in which he had supposed every ray of intelligence obliterated, suddenly brighten up after years of thoroughly diseased mental action, and speak rationally and intelligently. Such cases are as rare as they are interesting, and it is about them that I wish to speak, illustrating the subject by a typical case that occurred in the New Hampshire Asylum. There is but little on this interesting matter in the text-books of insanity. The subject itself, however, is well worthy of investigation, for the study of such cases may throw some important light on the pathology of one of the most obscure diseases, and may also add something to our knowledge of normal mental action.

The tendency of the latest investigation is to prove that mental action is developed through the activity of the nervous system; that chemical and cellular change in that system always precedes the evolution of thought. This leads us to the conclusion that insanity is a physical disease as much as pneumonia or pleurisy. Disordered mental action is dependent on disordered nerve tissue. I think nearly all alienists of the present time subscribe, in the main, to this view of the physical basis of mind. But any specialist who has lived among the insane recognizes the difficulty of establishing a perfect analogy between cases of mental and ordinary physical disease. Indeed, we seem to know as little about the pathology of insanity as we do about its morbid anatomy; and probably the same mystery that surrounds mind in general will always to a greater or less degree obscure it when diseased.

That the analogy between mental and ordinary physical disease is not complete is very evident. A man who has had paraplegia for three years does not suddenly take up his bed and walk, and yet a man's mind may be so diseased that not a single normal thought may be evolved for years, and, owing to the disordered state of his intellectual system, the man may have sunk into a condition worse than that in brute life, and yet, suddenly, after years of such diseased action, that same man may give utterance to sound thought, and may call into perfect play some of the higher attributes of mind, such as memory, realization of time, consciousness of his own condition, etc. It is as if a man with advanced locomotor ataxia should suddenly, perhaps for a few minutes only, arise and walk naturally. There is evidently something in the pathology of insanity that we have not grasped. We can understand tolerably well the ninety and nine cases that have chronic mental disease, and die, either in their thoroughly demented or maniacal condition, without uttering an intelligent idea. We can, to a certain extent, understand how there may be cases of recurrent mania, in which the patient runs through a more or less acute excitement, recovers, and breaks down again. Every hospital has its circulatory cases, and physicians are able to predict with great certainty in some cases the date of a fresh attack. But it is not to these that I allude. I refer to the cases in which the attributes of mind seem to have been destroyed, to cases in which, of the three factors of mind, namely, feeling, volition, and thought, feeling and volition, at least, seem to have been obliterated. In short, we find it extremely difficult to understand how it is that a man with chronic mania or dementia, in whose mind there does not seem to remain a single rational idea, how such a man may suddenly come back to himself, as it were, and speak intelligently.

With these few ideas in mind, I wish to outline as briefly as possible the clinical history of Hiram Gore, and to discuss the peculiar features of his mental condition. Gore was a native of New Hampshire, married, forty-two years of age, shoemaker. He was admitted on the 24th of May, 1877. Had been insane once before. The attack had been of one week's duration before admission. About ten days before, he had had some difficulty with a neighbor, and attempted to shoot him, for which he was arrested, and committed to the jail in Portsmouth. After his arrest he had been growing more excited, and for two days previous had been completely maniacal, violent in language and conduct, destroying everything he could lay his hands upon.

The report of May 30th reads: Since admission has been thoroughly maniacal, talking a greater part of the day, but resting a portion of the night; talks in a rattling, disjointed way, with no sense or connection. Has torn his shirts, and will not keep a thread on him; has also destroyed more or less of the bed-clothes, and pulled out the straw from his bed, and scattered it upon the floor. Is thin in flesh, but eats well.

June 1st. Continues much excited, and remains in his room; will keep no clothing on, and consequently is permitted to walk his room without any; seems to bear his excitement well, has a flourishing appetite, with regular bowels, and holds his flesh.

June 6th. An attempt was made to dress him, and allow him to stay in the hall, but as he immediately tore his clothing, canvas mittens were used; these seemed to quiet him a little in his actions, although he did not for an instant cease his constant, incoherent talking.

June 20th. Has been in the hall for several days only wearing mittens occasionally.

June 26th. Became more violently excited; is full of insane pranks. Attendant entered his room, and at first could not find him, but a little search disclosed him inside the straw bed; he had crawled inside the mattress, buttoning it after him. From this time on Gore grew worse. He became the most persistently maniacal person I ever saw. Sedatives were tried in vain. Both day and night he kept up one prolonged and continuous state of activity; for a few moments only would he catch a little sleep. Immediately on waking he would commence his incoherent speech. Still he ate heartily of whatever was given him. In his habits he became perfectly bestial. He seemed in appearance and actions devoid of every ray of intelligence. This state of things continued until the summer of 1880. He then began to show signs of exhaustion. Notwithstanding that he was so weak he still kept up his incoherent talking. Began to have abscesses form over his body. Became excessively emaciated. In August a diarrhoea appeared which could not be checked. He gradually failed in strength, although he still continued as wildly incoherent as ever until the morning of 13th of October, 1880. On this morning the attendant entered his room, and in his usual way said to Gore, "Good morning, Hiram," when, to his astonishment, Gore looked at him with an intelligent expression, and said: "I want to die. I feel ready to die. I have suffered for three long years, and I want to go where I can rest." These were literally the first intelligent words the patient had uttered for three years. He repeated these words or something similar during the next few hours, but he seemed to be gradually sinking. Occasionally he rallied, and then his face would lighten up, and a countenance that during his whole residence in the asylum had been a blank wore an intelligent look. There seemed by his actions to be something on his mind that he wished to say, but he appeared too weak to say all that he wished. He did speak, among other things, of his wife, and of trouble he had had with her and his daughter, giving the name and age of the latter. When the attendant went out of his room the patient would call him back and say there was something he wished to tell him, but he did not seem able to express himself. He gradually failed, and died about nine P. M. of exhaustion. Until he became too weak to recognize anything he still appeared intelli-

gent, and seemed to make an effort to make himself understood.

I wish now to briefly analyze the condition of Gore's mind, attempting to ascertain the character of its diseased action, and also to ascertain what faculties were left unimpaired, and what were apparently destroyed.

First in regard to the character of its diseased action. His cerebration was almost wholly subjective. Sensations imparted from his environment had little or no effect in exciting ideas or perceptions. He did not even have delusions excited by persons or objects about him. He would look at you vacantly or about the room all the while talking most incoherently. Scattered, detached words, names of individuals he had once known, followed each other in quick succession; but not a single idea was expressed. Those words evidently related to parts of old ideas and associations that had been previously stored up in his mind when he was well; now they came tumbling out incoherently without representing any idea. What I wish especially to emphasise is that his mind merely acted on what it had received in the past; the present was as nothing to him. In the second place it would seem as though something within the cerebral centres was keeping up a constant irritation, causing old ideas, old impressions, to be continually aroused and brought to consciousness; but they were so rapidly excited and brought in view, and succeeded one another so quickly, though without sequence or logical connection, that language was not capable of uttering them intelligently. One part of an idea was no sooner expressed in language than another idea was called up and the expression of the new idea crowded out the expression of the old. So much for the character of the mental action in this case. Now let us see what attributes of normal mind were still possessed by this diseased mind. We shall find present (1) consciousness, (2) perception of time, (3) memory. We shall find in abeyance volition.

(1.) Consciousness was not destroyed. It was through consciousness that he evidently made an attempt to express the rapid flow of ideas and perceptions that took place in his brain. And when at last after three years of almost continual incoherence his brain, apparently exhausted, refused to send forth ideas, then through this same consciousness we find that the man really was exhausted, and that he welcomed death as a speedy relief.

(2.) The patient possessed a knowledge of time. The knowledge of time possessed by the human mind is, when analyzed, found to be a very complex idea. The lower animals are doubtless unable to measure time that has passed. We hear of remarkable instances of tow horses on the street railway that seem to know exactly when the day's work is over, and when the last trip is made direct their steps toward the stable. But this conception of time in that case is undoubtedly due to the fact of a certain amount of muscular exhaustion and a certain amount of hunger which, by recurring day after day, has led them to feel that at about such a time when they experience such and such sensations, that is the time for leaving off work. But the human conception of time — of a year for instance, — is a far more complex act. First there is a day, then a night; then seven of these days and nights make a week. Four of these weeks make a month. Three of these months make a season. Twelve of these months or four of these seasons make

a year. All this is a very complex idea, and to be able to comprehend it one's mind must recognize the change of day into night, and night into day; and the change of summer into autumn, and autumn into winter, and so on. So that our patient's mind was in a more or less receptive state after all. And though he seemed to indicate a condition of mind lower than that in brute life, he still possessed mental attributes higher than any possessed by lower animals.

(3.) Memory. Memory was not by any means impaired wholly. We have already alluded to the fact that detached ideas, evidently relating to the man's past life, followed one another in rapid succession for three years. When now this incoherence suddenly ceased, and ideas were not pressed forward in this rapid, confused manner, the man looked up intelligently and remembered the past, remembered that he had been three years in a state of disease, and even recalled the circumstance of domestic trouble. And here is where the pathology of such cases confronts us. If there is actual disease of the nervous structure of the brain, just as there is actual disease of the cord in locomotor ataxia, or of the kidney in Bright's disease, why should the diseased organ suddenly act normally in the one case and not in the other? Why should the brain after years of diseased action suddenly evolve normal intelligent thought? The cord never regains its normal functions in locomotor ataxia; nor the kidney its function in chronic Bright's disease. Evidently the analogy is not as perfect as it seemed to be. We suppose the brain to be structurally diseased, and yet suddenly the normal action of mind asserts itself and ideas are rationally expressed. We almost feel driven to the assertion that in such cases as these insanity is not a structural disease, but rather that the mental disturbance is of a functional character.

So much for the faculties of mind that were preserved in our case. Of powers that were in abeyance we have to record volition. To all outward appearances this man no more exercised will power than a vegetable. As regards his thoughts will did not appear to control them in the least. The result of this was that for three years he did not have a single connected thought. As regards his actions will appeared to exercise no influence whatever. The result of this was that he would remain for hours in constrained and uncomfortable positions, that he tore and dashed about his room much as a wild bird would do, utterly regardless of self. But most remarkable of all is the fact that in his innermost consciousness the man suffered. He not only was simply exhausted and worn out, as is a piece of machinery after excessive use, but he was cognizant of the fact. He suffered, as he tells us, for three long years: and though he knew it still he could not control the terrible disease that overpowered him. Will power was lost. In these conditions of disease it would almost seem as though the patient lived a double life; his *ego* which seems to lie back of all, and is observant of all, and yet cannot control the mental state; and then his diseased mental self which rushes wildly on refusing to be controlled by either will or feeling.

The study of such cases would seem to point to one thing, namely: that though the centres of cerebration may be so affected that normal thought is an impossibility, nevertheless that higher, more immaterial mental state, that condition of mind which we call the *ego*, the conscious self, exists undiseased in some of the

most hopeless forms of insanity. And though for years it may seem to have disappeared, and to have lost influence over the centres of thought, nevertheless it does exist and, as in our present case, may assert itself in the midst of the greatest mental and physical dissolution.

## THE WATER SUPPLY OF BOSTON.<sup>1</sup>

BY HENRY J. BARNES, M. D.

THE public supply of water for the city of Boston has so far improved that we can once more drink without disgust, although it is still highly discolored, and there is a disagreeable smell, particularly in that drawn from the hot-water faucets. The change took place during the cold weather in the early part of December, and it is reasonable to ascribe this to the weather quite as much as to the fact of Farm Pond being shut off. For just before the new channel was finished around the margin I could not detect the bad taste so familiar in Boston in the water of this pond. Besides we did not get the good water from Basin No. 2, as promised by the Water Board, for an accident to the main, laid in the bed of Basin No. 1, necessitated the mingling of the water of the two basins before it could be used through the new channel, and the analysis of the water of No. 1, made by Mr. Remsen, November 5th, prompted him to classify it in point of impurity with Farm Pond, Bradley Basin, Pegan Meadows, and Basin No. 3. His subsequent discovery of spongilla in Farm Pond seems to have so occupied public attention that the filthy conditions of the other basins where no sponge has as yet been found have been lost sight of. To emphasize the importance of these other basins as factors in polluting the water I invite your attention to this subject, and that you may be better able to follow the discussion I will describe first the relative positions of the basins of the Sudbury River system by the aid of a diagram.

SUDBURY RIVER SUPPLY.

1, Basin No. 1. 2, Basin No. 2. 3, Basin No. 3. 4, Farm Pond drawn down. 5, Farm Pond. 6, Distribution of spongilla. 7, New conduit to Chestnut Hill. 8, New channel. 9, Main connecting Nos. 2 and 3 with Farm Pond. 10, Sudbury River. 11, Temporary dam. 12, South Framingham. 13, North division Old Colony Railroad. 14, Boston and Albany Railroad. 15, Stony Brook. 16, Upper gate house. 17, No. 3 drawn down in the summer of 1881.

<sup>1</sup> Read before the Suffolk District Medical Society, December 31, 1881.

This system of supply is naturally good. Sudbury River compared favorably with all the many systems examined when Boston debated in 1872 and 1873 which to adopt, and finally, when narrowed down to a question as to whether it or the Charles River should be taken, its freedom from sewage settled the debate in its favor.

Mr. Davis, the city engineer, at the time reported in City Document, 29, page 28, 1873: "There are various reasons for believing Sudbury River water to be unusually free from deleterious matter, either in solution or held in suspension. Such was the testimony of all persons consulted, this water being used for many years for bleaching, and noted for its fitness, indicating it was free from color," etc. Again, on page 33, Mr. Davis writes: "The usual water of Sudbury River is pure and clear." These were his conclusions, although at the time there was some discoloration, due, as he says, "to the taking up of vegetable matter during a freshet after an unusually dry summer." Professor Remsen's more recent examination supports this opinion so far as it goes.

Stony Brook does not seem to have received so much attention, presumably for the reason that not even a suspicion of impurity has ever been raised in regard to it. A farmer living near it, just above No. 3, tells me he "has always known the water to be clear and good." I can find no authoritative statement that either receive any considerable amount of sewage, but, on the contrary, many reports that it does not exist to any appreciable extent in the water of either of these streams.

There remains the natural basin of Farm Pond to describe, which before the introduction of Sudbury River water was pure and clear. It received the drainage of a very limited area of the flat territory around, not even a good-sized ditch emptied into it, and its outflow was into the Sudbury River. The clean stone and gravel bottom could be seen from many parts of the surface. At either end there is a peat bog of several acres, and in the deepest parts considerable mud, which the Water Board state measures thirty feet in some places; but this may be fairly questioned when we take into consideration that it is a shallow pond, situated on a plain which abounds in quicksands as easily penetrated by a pole as mud would be. I have been familiar with the pond for the past twenty years, and have always known the water to be pure and clear until the water from No. 3 was let into it, when it became dark and turbid. Mr. Davis, in City Document 29, page 26, 1873, says "that Farm Pond being a natural basin, but little work is needed to put it in good order."

The water of this supply was first used in the summer of 1872 by constructing a temporary dam on the Sudbury River just below the outlet of the pond. At the other end a channel was dug to conduct the water into Beaver Brook, a tributary of Lake Cochituate, and by these means the lake was supplied and kept full most of the time until the completion of the new conduit connecting Farm Pond directly with the Chestnut Hill Reservoir, and for seven years we had no trouble with this water. The local engineer reports in City Document 79, page 128, 1879, "that the surface of Lake Cochituate has by this means been kept higher than usual, and the quality fully up to the standard of previous years."

The trouble with the water began after the comple-

tion of Basin No. 3. This basin was filled for the first time in the winter and spring of 1878 and 1879; the following September there was a general complaint throughout the city of bad-tasting water. Algae were found in all the basins, and Mr. Davis, in one of his reports to the Water Board, said it was conveyed from No. 3 to the others. Professor Nichols attributed it to vegetable matter taken up in the storage basins.

Let us now examine No. 3, and notice what changes took place there. I have a sectional view of this basin as it appeared after the water was drawn down last summer.

SECTION NO. 3.

1, High-water line. 2, Bed of brook. 3, Vegetable mould. 4, Clean gravel bank. 5, Mud banks and flats. 6, Water line acting on mud banks.

Mr. Davis anticipated this effect, for in Document 29, page 43 of his report in 1873, he urged the rapid construction of the new basins that they might have time to decompose the vegetable matter," and on page 35 he says: "No. 3 includes an extensive swamp and lands supporting a rich vegetation, which it is desirable to have removed by grubbing and excavation, as it will otherwise have to be gotten rid of by a slow process of decomposition, which will be apt in the summer months to deteriorate the water." One would suppose that with this recommendation and the experience the Water Board had gained by disregarding it they would seize the first opportunity to free the basin of this material. Not so, however; they caused it to be refilled to the line of clean gravel, and it purified itself during the winter. The next year it was drawn on, but to a limited extent. There were some algae, but the water was fair during the year. Last spring, being full to the line of clean gravel, it was so good that with water from Basin No. 2 the entire supply of the city, save that furnished by Mystic River, was taken from this source. The effect was to lower the water rapidly in No. 3, and expose vast mud flats and banks in the early summer, which, exposed to the hot sun, became very offensive. The alternate rise and fall of the water, the waves and the currents, assailing the banks, washed away great quantities of these overflowed farm lands, which for many years had received the products of the barn-yards, and were full of dead animal and vegetable material. The earth-worms alone, Mr. Darwin tells us, number twenty-six thousand per acre, and their excrement amounts to ten tons a year. Beetles, moles, grasshoppers, sewer-bugs, and many other forms of animal life make up material undergoing the process of decomposition. Do you wonder that these flats have been infested by large flocks of crows, here doing excellent work as scavengers? Then as to the decaying vegetable matter, do any of you as boys remember the opening of a vegetable cellar in spring, and its disgusting stench, or the decay of hay about the barn-yard? Is it to be wondered at that

Mr. Remsen should say "the water tastes of the pignep," and ought not to be used, or that the citizens of Framingham should complain of the smell?

Now let us trace this filthy water to Boston. It is conducted, as I have shown you, through Basin No. 1, without mingling with its waters, into Farm Pond. Drawn from the lowest point of the basin, the greatest amount of suspended material is swept into the pond, there to spread over this shallow sheet of water, to steep and macerate during the summer; much is deposited, for the current is slow, and since the pond has been drawn off I have taken pains to measure the depth of the deposit.

About the upper gate house, an inch at least overlies the clean gravel and the new channel cuts through it all the way to the gate house at the other end of the pond. As you approach the natural channel it is much deeper, there are three to six and even ten inches of this material filled with sticks, roots, and blades of grass, such as you will see in one of the bottles I show, the presence of which leads me to infer that it is recent. Mr. Van Vliet found this mud to emit very offensive gases, another fact tending to show that the deposit is recent.

The spongilla was found by this gentleman distributed only in that part of Farm Pond which Mr. Wightman, the present city engineer, pointed out at a meeting of the Natural History Society as being the natural channel between the two gate houses, and it was found in greatest abundance about the upper gate. Professor Hyatt, at the same meeting, described the habit of the spongilla as attaching itself to hard surfaces and living by absorbing quantities of water from which it selected its food. I find in Griffith and Henfrey's Micrographic Dictionary that algae are its chief nourishment. Is it not fair to infer then that the luxurious growth of the spongilla in Farm Pond subsists on the organic material introduced from "pignep," and that it is living at the expense of quite as noxious material as itself?

Farm Pond is not capable of acting as a settling basin, for all the material from it comes into our houses in Boston to clog the filters and pollute our tanks. I found in mine a deposit of mud three quarters of an inch deep, which a short time after being taken out became very offensive; half a dozen or so of coagulated masses partially suspended near the bottom, and the sides were lined with a soft slimy-feeling substance which under the microscope showed abundant algae. The tank was at the top of my house and fed by a faucet governed by a floating ball insuring a slow current, and thus giving the most favorable chance for the material to settle in the pipes, and be drawn off through the faucets in the lower stories. It was cleaned and securely covered eight months before. If these conditions suggest anything it is that the supply is contaminated first in the new basins by taking up decomposing animal and vegetable matter. Mr. Davis hoped that the new basins would be "completed sometime before it would be necessary to use the water, that they might assume the character of natural ponds" by this process. Professor Nichols recognizes the dangers of vegetable matter in storage basins when he writes, "deposit in storage basins goes on continually and is preparing evil for the future as this deposit undergoes a slow process of decay."<sup>1</sup> Instead of a slow

process of decay these vast lands were uncovered early in the summer and the most rapid process of decay and decomposition possible was the result. Professor Edes, of New Jersey, examined Boston's water last summer, and states in brief, "that it contains pollution amounting to seventy per cent. above the limit of health, and that he found it abounding in decomposing organic matter."

Does any one but Boston's Water Board pretend that all this filth comes from the once beautiful Farm Pond? No, gentlemen, it comes from the new basins, and you can see it, passing as I did, December 10th, when the color of the water in the new channel cut around Farm Pond was that of good coffee.

In 1854 Dr. Jackson attributed the trouble in Lake Cochituate to the decay of vegetable matter. In 1873 the Water Board having Mystic in charge, "congratulate the city on having provided additional pumping power and enabling them to draw off the water, giving a long desired opportunity to clean the basin." The Mystic basins were chiefly built like those on Sudbury River, and you know how often complaint has been made of the bad taste of the water. In dry seasons vast mud banks here have been exposed, I am told.

Cochituate has been drawn low several times, exposing the mud particularly in that part of the basin next to Natick, which receives the sewage of Pegan Brook. It can hardly be doubted but that this has operated to vitiate the water of Lake Cochituate. Westborough, Mass., has had trouble with its system, and the engineer under whose charge the work was done, writes me that he attributes the trouble to vegetation left in the basin, the gentlemen representing the town disregarding his recommendation to remove it. Newton, taking Charles River water, excavated a basin something like one thousand feet long, from which the water is pumped, and it has always been good.

Mr. Wilde, member of the Water Board having the care of Spot Pond, tells me "the trouble was caused there three years ago by the exposure of vast mud banks during a dry summer. The following spring the ice which had frozen to this mud raised a great quantity of it which was distributed in the water when the ice melted." Albany, taking its supply from Lake Rensselaer, thought to increase the area by raising a dam, a bad taste of the water was the result, and Professor Chandler considering the decaying vegetable matter to be the cause advise its removal, which was done and relief followed. The basins at Chestnut Hill gave us no trouble when first constructed, for the wash of the banks was guarded against by a clean stone lining. The water of one of them is said to have had a bad taste for a short time in 1875. I do not attempt to explain the trouble, but in view of its receiving water from Lake Cochituate through the old conduit which Mr. Wiggin reported, after an examination, "to be lined with a growing substance resembling sponge," and Mr. Davis subsequently reported "the sides covered with a vegetable growth," it is suggested only that the trouble might be introduced from this source. The late Dr. Jacob Bigelow said "that the water of Sudbury supply would not be good until the basins were cleaned," and Professor Sharples, in an interview published in the *Herald*, November 21st, says, "I do think that in every case, so far as reported, the smell and taste can be traced to decay of vegetable or animal matter."

You will naturally ask why the water of basin No. 2

<sup>1</sup> City Doc. 38, page 135, 1872 or 1873.

on Sudbury River should be good this fall while Nos. 1 and 3 were bad. It differs from them in that its banks are steep and there are no extensive mud shoals to be exposed when the water is partially drawn off. It is a small basin supplied by the considerable amount of good water flowing in Sudbury River. The steep banks have been effectively washed down to the clean gravel, and it has been kept full except for a short time in the early part of last summer.

I do not discuss the theories advanced by able men as to causes of trouble, for I admit that all save "the fish story," have an abundance of evidence to support them.<sup>1</sup> But I do claim that they each depend on the organic matter taken up in the basins decomposing and furnishing nourishment for the many forms of noxious life found in our water, and which impart to it taste, smell, and color by their decomposition.

## RECENT PROGRESS IN DISEASES OF CHILDREN.

BY T. M. ROTCH, M. D.

### CHLORATE OF POTASH POISONING.<sup>2</sup>

THE use of chlorate of potash as a household remedy, especially for children, is so common, that it is well to note the somewhat frequent occurrence of the fatal effect of overdoses of this drug. Dr. Sadow, of Leipzig, reports the case of a boy fifteen and a half years old, convalescent from diphtheria, who was attacked with symptoms of poisoning after swallowing a solution of chlorate of potash and water amounting to from twenty-five to thirty grammes of the salt. On the night of December 24th, after drinking the mixture, he was seized with frequent vomiting of dark green masses very similar to thin fecal discharges; at midnight a small quantity of dark urine was passed; at daybreak the patient was noticed to be jaundiced. December 25th, nine A. M., the temperature was 37° C.; pulse 124; weak; respirations 40. Skin cyanotic; lungs normal; heart sounds normal, excepting that the first sound was somewhat prolonged; some epigastric tenderness; liver enlarged and palpation both in this region and over the spleen, which was also enlarged, caused great pain. There was suppression of urine, none having been excreted since the small quantity passed in the night, the bladder having been found by the catheter to be empty. The patient complained of weakness, præcordial anxiety, and dyspnoea; the mind was clear; the vomiting continued every fifteen minutes. The anuria continued until December 26th, four A. M., when a few drops of dark-red, dense urine were passed accompanied by burning pain; the vomiting continued. Temperature 38.2° C.; pulse 104; respirations 28. At four P. M. the patient felt a little better, but a slight convergent strabismus of the left eye was noticed. The symptoms continued although stimulants were freely given and transfusion resorted to twice, and on the morning of December 28th the patient died, his mind remaining clear to the last, and death resulting gradually from increased weakness of the heart, accompanied by dyspnoea and subjective feelings of coldness

and paralysis of the feet progressively extending upwards. The post-mortem appearances, besides showing intense catarrh of the gastro-intestinal canal and enlargement of the liver and spleen, were especially interesting as showing the effect of the chlorate of potash on the blood, which was similar to the results obtained by the experiments of Marchand with this salt, the blood having the characteristic brown color (lackfarbig) and the density of syrup and the red corpuscles being especially affected, becoming pale and glutinous and gathering together in irregular clumps. A large quantity of reddish-brown fragments, supposed to be hæmoglobin, had been found in the urine passed on December 26th, and on examination of the kidneys these same masses were found in large numbers, especially in the convoluted and straight tubules, only sparingly in the glomeruli, and not at all in the interstitial tissue. It was also noticeable that there was no sign of an inflammatory condition anywhere in the kidney, the interstitial tissue being absolutely normal, and the epithelial cells of the tubules, although compressed by the masses of hæmoglobin, showing no trace of cloudiness or infiltration.

### HYPERTROPHY AND DILATATION OF THE HEART DURING SCARLET-FEVER NEPHRITIS.<sup>3</sup>

Dr. Oscar Silbermann in an elaborate article on this subject speaks of the comparatively few observations which have been made in this direction up to the time of Friedländer's investigations during the year 1881. This author found, on examining a large number of cases of nephritis occurring during attacks of scarlet fever, decided hypertrophy of the heart combined with dilatation, in some cases both sides of the heart being equally affected, but usually only the left side; he also made a careful comparison of the weights of hearts in healthy children with those who had died of scarlet-fever nephritis. In only a few cases was there found a partial fatty degeneration of the muscular fibres; the endocardium, pericardium, and blood-vessels were normal. There was no doubt according to these observations that the cardiac affection was related to the postscarlatinal nephritis and not to the scarlet-fever process itself, as the hypertrophy was never found where the children died in the early weeks of the disease. Silbermann draws attention to the short period which intervened between the first appearance of the nephritis and the consecutive heart hypertrophy, in many of the cases the time being not much longer than a week, and he refers to the physiological observations of Beneke and Gerhardt, which showed that the heart between the third and eighth year is relatively larger than in adult life, and that at this age there exists a physiological hypertrophy of the left ventricle, caused by a continuance of the aortic narrowing in the neighborhood of the ductus Botalli, and Silbermann thinks that this tendency to physiological hypertrophy between the ages of three and eight may account for the speedy dilatation and hypertrophy following the acute nephritis of scarlet fever, the cases in which it occurred being respectively four, five, six, three and a half, and six years old.

### HYSTERICAL ANALGESIA.<sup>4</sup>

Dr. Thomas Barlow draws attention to the fact that analgesia is not a symptom confined to young women

<sup>1</sup> Since writing the above the *Journal of Chemistry* reprints the "fish story." I saw half a peck of fish taken from Farm Pond by a net at the time it was drawn down; they were all lively and apparently healthy.

<sup>2</sup> *Jahrbuch für Kinderheilkunde*, October 4, 1881. S. 311.

<sup>3</sup> *Jahrbuch für Kinderheilkunde*, October 4, 1881.

<sup>4</sup> *British Medical Journal*, December 3, 1881.

living in the wards of a hospital where they are objects of repeated experiment and demonstration, but that it can be found in very young children, who manifest other signs of the hysterical neurosis, and he considers that the elements of feigned disease and expectant attention are less likely to embarrass us than in adults, citing the case of a little boy two years and nine months old, who had the skin between the roots of his fingers pricked with a needle, precautions having been taken that he should not know what was to be done. He neither winced nor withdrew his hand. When, subsequently, one side of his face was pricked there was the slightest possible play of his features. When the other side was pricked he cried. There was no reason to suspect any organic disease of the brain. The boy had been brought into the hospital on account of fits which were unquestionably of the hysterical type. They had followed upon a fall, which had not bruised but had frightened him.

He then reports a series of eight cases, which he had tested by the prick of a pin, the pinch of a pair of dressing forceps and the application of strong faradism. Great differences were noted in the degree of analgesia and its distribution. In the most marked case strong faradism was tolerated with complete indifference on one side, while a moderate current applied to the other side elicited an expression of pain, although not a loud one. The application of strong faradism for many minutes on a second occasion at length brought out a slight expression of discomfort. In another case strong faradism was tolerated with perfect indifference when applied to either leg; this was continued for a quarter of an hour, when there was a gradual return of sensitiveness, and at length some expression of slight discomfort. In another case, some distress was shown directly on the application of the faradism, although a needle had been pushed into the skin without the child withdrawing the limb. In a fourth case, the needle was tolerated for several minutes and then the limb was slowly withdrawn, but without any cry. As to distribution, although it was found to be more prominent on one side than on the other, yet it was usually a general symptom. It was more marked in the limbs than on the face. In all the cases there were symptoms either related or observed which strongly pointed to hysteria. In one case there was paraplegia, which had lasted for nine months without any wasting and which gradually cleared up after the use of faradism for a quarter of an hour. In the others there were convulsions, which in several cases had followed what might be called a moral shock. In regard to the convulsions, it was doubtful whether in any case there was loss of consciousness, although in some of them the patients fell down suddenly as though they had been shot. In most cases there were coordinated movements. Opisthotonos and to-and-fro movements of the trunk were marked features. Movements of the eyelids were noted, but no facial distortion, and in no case were the fits decided, so far as could be ascertained. The analgesia had not been tested in these children before they were brought to the out-patient room.

Of the eight cases above spoken of six were girls and two boys. The ages of the girls were, respectively, three years, five and one half years, eight years, nine years, nine and one half years, and eleven and one half years. One of the boys was two years and nine months old, and the other nine years. Dr. Bar-

low considers that a study of these cases supports the view that in the hysterical neurosis there is a torpid condition of the sensory part of the brain. In extreme cases this condition may involve the centres of the special senses, whilst in the very slight cases the only abnormality may be more or less blunting in the appreciation of ordinarily painful impressions. The sensorium of the hysterical patient may no doubt be awakened by many peripheral stimuli, the best of which is probably cutaneous faradism. The importance of the analgesia in these cases appears to rest entirely on the fact that it is a valuable aid to the diagnosis of hysteria, and hardly merited any special treatment beyond vigorous and well-regulated exercise of mind and body.

#### CHOREA.<sup>1</sup>

In connection with the two hundred cases of chorea analyzed by Dr. H. C. Haven, and reported in this journal September 29, 1881, we notice a series of one hundred cases treated by Dr. William Strange, of the Worcester Infirmary.

Dr. Strange concludes that the disease is to a considerable degree one of poverty, that it occurs usually during the period of active growth or during that second period when, the growth having been finished, often prematurely, the constitutional powers have not yet acquired a proper degree of consolidation and the nervous centres sufficient steadiness.

In regard to sex and age the same results were deduced from both series of cases, females being found to be especially susceptible, and the age from six to eleven years being most common.

Dr. Strange regards chorea as a pure, non-organic neurosis, implying by the term that it has no anatomical or true pathological basis, post-mortem examinations not having given to it any definite morbid anatomy, and his review of these one hundred cases makes him look upon it as merely a functional disturbance with alteration of nutrition of the nervous centres; he also says that the comparatively few fatal cases on record afford no clew to the true pathology of the disease, because it is clear that the complications of other distinct diseases with the chorea were answerable for the more considerable of the morbid changes observed. The writer next discusses the question of aetiology. He says that, looking upon chorea as essentially a disease of debility, we are not surprised to find in almost every case a want of power to restrain as well as duly to coördinate muscular movement. Now in all this there is surely debility or deficiency of nerve power. Over-action, we know, always indicates weakness, pre-existing or consecutive. With regard to the existing causes of chorea, he says that when the mobile frames of young children have been subjected to the influences indicative of poverty and weakness, it requires but a slight additional disturbance to throw the nervous apparatus out of gear, and to cause its movements to escape from the control of the will. Chief among the exciting causes is fright, which may operate in various ways, some simple, some more continuous and complicated; it need not be sudden, though that is generally the case. Ill-tempered parents, especially the mother, may keep a child in perpetual trepidation and dread of punishment for unavoidable disasters. In several instances worms were found in the intestines, but when these were got rid of the chorea which they were supposed to have excited had still to be cured. Dr.

<sup>1</sup> British Medical Journal, July 16, 1881.

Strange then discusses the question as to whether chorea is frequently dependent upon previously existing disease of the heart, rheumatic or otherwise. He says that in some fatal cases fibrous vegetations were found on the cardiac valves, and minute particles of these growths have doubtless at times become emboli, and given rise to minute hemorrhages in the brain. But if any such dislodgment were of frequent occurrence in cases of chorea, we ought to find signs of embolism in various other organs including the skin, which is not the case. The combination which he has observed in a few cases is, first, rheumatism in early life; next the heart is affected; then the patient recovers so far as such patients ever recover. Some time afterwards, perhaps two or three years, the same young person is brought to the hospital suffering from chorea. In this case it is impossible to say that minute fibrinous particles have not been detached from the cardiac valves or from the tendinous chords of the ventricles, but we have no proof of it. Indeed, if this were a frequent cause of chorea symptoms of this disorder ought to follow the heart affection more quickly than is generally observed, when, in fact, these minute fibrils are soft and fresh, and easily detached from their bases. The chorea in the above instance then being relieved, the patient ultimately dies of the original mischief done to the heart. In this case it is not more reasonable to suppose that the chorea is the result of disordered nutrition of the nervous substance, caused by the irregular and defective circulation which almost always occurs in such cases? It must be confessed, however, that there is a difficulty in accounting for cases of hemichorea upon the general principles of defective nutrition, for defective nutrition, unless it be caused by some local circumscribed obstruction, should operate on the whole nervous system alike. The symptoms, then, of chorea are those of incoordination and defective inhibition. These are the results of brain starvation, caused by morbid products which cut off the proper supply of blood to the nerve cells. The force residing in the brain cells is defective, owing, probably, according to Andral, to their defective aggregation or to want of firmness in the conducting white substance, or to both. The rapidity with which proper food and medicines calculated to give tone to the nervous system act in curing the disorder is the proof from treatment which confirms the verity of this view of the pathology of the disease.

The writer then says that if the above ideas as to the nature and causes of chorea are true little need be said as to the medicinal treatment of the disease. There being nothing special in the coarse pathology of chorea no specific remedy is required, or likely to be found if required. Dr. Strange has treated a large number of cases without any drugs whatever, and simply with three to six ounces daily of ordinary port wine. By this treatment a cure was effected in the average of cases in from three to six weeks, which certainly compares very well with the success attained by the arsenic treatment of chorea.

—There is ground for hoping that some thorough system may be adopted for the disinfection of old rags used for manufacturing paper, etc., since cases of small-pox have lately again been shown to have had their origin in this source of infection. The rags imported from Egypt and Asia Minor should be especially looked after.

## Hospital Practice and Clinical Memoranda.

### ST. LOUIS HOSPITAL NOTES.

REPORTED BY J. B. SHAPLEIGH, M.D.

#### TWO CASES OF GANGRENE OF SCROTUM.

**CASE I.** J. O. Male. Age forty. Irishman. Fell astride a joist on the day before entrance which was July 23, 1881. The scrotum, penis, perineum, and inside of thighs were much discolored and oedematous. A diagnosis of hematocoele had been made at the examining office but no fluid was found in the tunica vaginalis thin enough to pass through the canula. Free incisions were made in scrotum and penis to relieve tension and prevent gangrene if possible. Patient was unable to pass his urine and on the day after admission an attempt to puncture the bladder through the rectum was made but failed. Bladder was then aspirated above the pubis and 1050 cc. of urine drawn off. On the fourth day after the accident the urine began to dribble through the incisions in scrotum, and continued so to do for about ten days, when the whole was voided at one time, still through the cuts.

For the first week the patient had more or less fever, and the scrotum soon showed signs of sloughing. Under tonics the patient improved in strength and the line of separation rapidly formed. This ran round the base of the scrotum close to the body and left the testicles entirely uncovered when the slough separated. They were each provided with a small, but neat, scrotum of their own by the granulations and the retraction of the new tissue drawing skin from abdomen and thighs. The urethra had been almost completely divided by the fall, hence the dribbling through the scrotum, and when the new scrotum had been formed the external opening of the fistula was just behind it, and was about 0.05 decimetres in length. This gradually closed but was kept from narrowing the canal of the urethra by the use of bougies. The man left the Hospital December 19, 1881, having been able for a week to pass his water through the entire urethra as formerly, by holding his legs together, otherwise it came through the fistula.

**CASE II.** G. L. Age fifty-four. Born in Vermont. Had always had fair health except a tendency to chronic diarrhoea. Had had a stricture of urethra.

Patient was admitted October 29, 1881, suffering from blood poisoning, resulting from gangrene of scrotum. His story was that he fell upon the sharp edge of a barrel, striking his perineum. The scrotum soon began to swell and turn black, and he noticed that he could not pass his water. On examination the entire scrotum was found to be gangrenous, and very tense. An incision was made in the median line and the cavity of the scrotum laid open. This was found to contain a large quantity of very strongly alkaline urine, and a rent in the urethra was found just in front of the bulb. Scrotum was stuffed with salicylic acid emulsion on oakum, and patient treated for septicæmia.

In the course of a week his condition was much improved and the gangrenous portion of the scrotum had begun to separate. Everything looked favorable, when a diarrhoea, very similar to that of phthisis, attacked the patient, and, in spite of all treatment, continued

until his strength was exhausted and he died. Up to within a week of death there had been continuous progress in the healing of the serotum. The testicles, which had been entirely exposed, had drawn up toward the pubes and were half covered by the advancing granulations. The opening in the urethra was almost closed and a few drops of urine occasionally escaped from the meatus. The recovery would, without doubt, have been as good as in the first case but for the fatal diarrhœa, a tendency to which seems to have been constitutional with him.

#### ACUTE JAUNDICE; DEATH IN FORTY-EIGHT HOURS.

CASE III. D. T. Irishman. Age fifty; entered the Hospital November 9, 1881, for an ununited fracture of the tibia dating back to March of same year. He had been walking on it with the aid of a cane since that time. Ends of the fragments were rubbed together and the leg put up in plaster stirrup. Patient had decided cirrhosis of liver and confessed to having been a hard drinker in former years, but not lately. *Had never had any dropsy.*

On Thursday, December 15, 1881, the man seemed as well as usual and went to bed apparently in good health. During the night he was attacked with nausea and vomiting. Matter vomited tasted bitter but was not saved for inspection. On seeing him, at eight A. M. Friday, I found him much jaundiced, the conjunctivæ and the whole surface of the body being of a bright yellow. He was totally unconscious of this and was surprised when told. He had no fever, and pulse and respiration were normal. His mind was unaffected. There was no pain except slight tenderness on palpation over epigastric region. Ordered podophyllin and dilute nitro-muriatic acid.

At ten A. M. there seemed no change except that the color was appreciably darker. At four P. M. found no change. Had had several evacuations of a watery character from bowels. Unfortunately these were not preserved.

On Saturday morning at eight o'clock found him comatose with labored breathing. Pulse full and soft, rather slow and evidently failing. There were no convulsions and patient died in coma in the afternoon, not more than forty hours after he was first attacked with nausea.

Post mortem was held eighteen hours after death. The body presented a uniform yellow color. The ribs were much expanded laterally, making cavity of thorax much broader than normal, nothing else unusual. Thoracic viscera normal. Slight pleuritic adhesions in right chest. Stomach and upper part of duodenum presented evidence of recent inflammation, the rest of the intestinal tract normal. Spleen somewhat enlarged and engorged with blood. Liver was a type of complete cirrhosis, much contracted and roughened; in size only about half the normal. Gall-bladder about half full of thick, tarry bile. Cystic duct partially occluded by same material. Common and hepatic ducts free. All the tissues were very yellow, even the marrow of the bones looking like butter.

The striking features of the case are the absence of any dropsy with a liver in this condition, and the occurrence of jaundice so rapidly fatal, and apparently without cause. The former may be explained by supposing the general venous system anastomosing with the portal system, sufficiently enlarged to allow a return to the heart of blood destined for the portal veins,

without its passage through the liver. This would prevent any backward pressure of the blood on the portal venous capillaries, and so prevent ascites. Of the cause of the jaundice I am ignorant.

## Reports of Societies.

### BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

WALTER CHANNING, M. D., SECRETARY.

OCTOBER, 1881. At this meeting, which was the fourteenth regular meeting, Dr. J. B. AYER reported

#### A SEVERE CASE OF MELANCHOLIA FOLLOWING PNEUMONIA,

of over two and one-half years' duration, carefully treated at home, and during the past few months showing improvement.

In connection Dr. Ayer alluded to the following subjects as of especial interest:—

(a) *Insanity following acute disease* is of quite frequent occurrence. Of 5116 cases in the McLean Asylum during forty-three years, sixty-two were stated to be of post-febrile origin.

It is important to recognize the early symptoms of insanity occurring in connection with acute disease, for it is sometimes possible by judicious treatment to avert an impending attack.

(b) *Climacteric insanity* generally takes the form of profound melancholia with more or less excitement. Its frequency compared with other causes is shown by the following table:—

Out of 5116 cases

51 were attributed to disturbances caused by menopause,

42 were attributed to disturbances of uterine disease,

167 were puerperal cases.

(c) *The rarity of recovery* after the completion of the second year.

Blandford mentions two cases recovering at the end of five and one at the end of seven years, and says that melancholia is the only form of insanity where recovery occurs after such a long period.

Blandford explains the symptoms of the disease as follows: "During the whole period the general nerve energy is in a state of defect, causing intense melancholy and consequent delusions. All the ideas are tintured by the prevailing gloom, but if the nerve force is restored the mind resumes its proper work unimpaired."

The state of stupor, he thinks, has a close resemblance to the dreaming condition, the brain being only partially at work.

(d) *Treatment.* Morphia was not given regularly. When administered it generally controlled excitement satisfactorily, and put the patient to sleep.

Chloral and conium used, but it was impossible to decide with how much benefit.

Hyoseyanus (Squibb's alcoholic extract), used principally in one and one half grain suppositories, had a decided sedative effect. After using for a few days they began to lose effect, but after waiting a fortnight they could be resumed with undiminished benefit.

Hyoseyania (Mercer's and Morson's preparations tried) one sixty-fourth to one thirty-fifth grain two to four times daily, was of service at first, but soon lost

effect. It did not justify the name given it by its favorites, "chemical restraint."

Among other sedatives the elixir of the valerianate of ammonium and scutellaria were of service, but bromide of potash was used most frequently, in doses of fifteen to fifty grains. It relieved cerebral congestion and quieted excitement. If the mania had been attended by less excitement bromide of potash would have been less freely indicated.

Iron and quinine were given from the outset, at which time it was administered with nourishment through the stomach-tube.

Laxatives were given constantly, but rarely were cathartics needed.

Nourishing food and a moderate amount of stimulant were insisted upon throughout.

(e) *Home treatment.* This subject is now discussed in an energetic manner in the London journals.

Hon. F. C. Walker writes that a considerable number of cases of insanity of over two years' duration, treated at home, have been reported to the Census Department.

In this case the house was converted into a hospital. Devoted, unremitting, and skillful attention was afforded for the patient's every need. At the end of five months, when the physical condition had improved, she was taken to drive, then to walk, and later to make calls upon her friends.

When morning excitement could not be broken up by drugs or by offering food during the night, she was taken to ride in the horse cars early every morning, a plan which was completely successful.

She soon began to knit and do light housework. Now her time is occupied between recreation and employment, and she is allowed little time to dwell upon morbid feelings.

Last summer she spent in the suburbs of Boston in a rented house, taking daily rides and long walks.

The writer believed that during the first year of illness asylum treatment would have been as efficacious, but during the past eighteen months he felt that association with other insane patients would have had a depressing effect, and the mere fact of being in an asylum would have kept her from working, for "*asylums, as now conducted*," according to the trustees of the McLean Asylum,<sup>1</sup> "afford little more than a place where patients can be isolated from society, kindly treated, and a watchful oversight maintained."

The writer mentioned his experience at the McLean Asylum in trying to induce convalescents to work, in which attempt he decidedly failed.

In closing he referred to the possibility of treating satisfactorily a case of protracted insanity at home, but dwelt upon the untold difficulties and expense attending such course.

NOVEMBER, 1881. Fifteenth regular meeting. At the meeting Dr. T. W. FISHER was chosen secretary *pro tem*.

Dr. C. P. BANCROFT read a paper entitled

#### NORMAL CEREBRATION FOLLOWING THREE YEARS OF DISEASED MENTAL ACTION; THE MYSTERY OF ITS PATHOLOGY.<sup>2</sup>

In the discussion which followed the reading of the paper, Dr. DENNEY remarked that it is extremely dif-

ficult to determine how much true consciousness remains in such a case. The recurrence of lucid intervals does not presuppose a return of the normal vigor of mind. The avenues of consciousness are apt to be obstructed more or less by sensory defects and impairment. The constant agitation and activity indicate disorder of the anterior portion of the cortex. There was probably an increased combustion in body and brain, as would probably have been shown by increase of hematoidin and diminution of urea. Pathology of insanity requires means of investigation not generally used. Sealing together of posterior cornua found after death indicated past inflammatory action, which is believed by some authorities to be causative of insanity.

Dr. C. F. FOLSON thought such cases not extremely rare. Consciousness is probably not so much diminished as it seems to be. He related a case of previous mania in which the patient seemed to take no notice of anything. But on recovery remarks made in the hearing of this patient were repeated. Sometimes the inattention to surroundings was due to delusion, as in a case of a man who thought he was dead, yet he would get up, eat, and return to his passive condition again.

Dr. COWLES reported a case of hebetude in a woman lasting a year. Once made a sensible remark and seemed clear for an hour or two and then relapsed into seeming unconsciousness.

Dr. FISHER mentioned several cases of recovery after long-continued and extreme mental disorder. The lucid intervals occurring in consequence of intercurrent physical disease, the cases of extreme dementia show that the mind is less deeply impaired than would appear. The ease with which many insane persons passed from consciousness into a trance-like condition was remarkable, some cases fluctuating day after day, between the two states.

#### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

OCTOBER 15, 1881. Dr. BAKER read a paper on

#### CANCER OF THE UTERUS,

which was reserved for publication.

Dr. C. M. GREEN spoke of the early age of many of the subjects of cancer of the uterus, and of a number of cases in Vienna in which the age was not more than twenty or twenty-five years. The operation there was essentially the same as that detailed by the reader, and cases were reported in which there had been no return of the disease for a number of years, varying from two to seventeen. As to the question of constitutional taint, Dr. Green cited the instance of a woman twenty-eight or thirty years of age, who was apparently perfectly well, yet in whom an examination revealed disease involving the entire cervix and extending into the body of the uterus.

Dr. ABBOT asked what had been the results when the entire uterus had been removed.

Dr. BAKER replied that the operation had been successful, and that the longest respite from the disease after that operation which he had seen recorded was a year and a half.

Dr. BLAKE said he should judge that the result

<sup>1</sup> Report for 1876.

<sup>2</sup> See page 76 of this JOURNAL.

would be substantially the same as that by the ordinary method of scraping with a sharp curette followed by the caustic, which, as far as he could see, accomplished as much as the knife followed by the caustic. Further, he would operate in any case where the symptoms were distressing, as a means of palliation, removing what he could and following the curette with chromic acid. Dr. Blake said he would heartily coincide with the reader as to the propriety of treating local symptoms in the virgin as thoroughly and directly as in the married woman, and that he believed it to be the duty of every physician to treat cervical ulcerations and abrasions whenever these came under his notice. Dr. Blake thought more attention should be paid to affections of the uterus and more care exercised in examinations and measurements.

DR. CHADWICK said that the operation by Dr. Baker was an advance in that it extended the number of cases to which surgical interference per vaginam was applicable. The results shown were impressive. The length of time since the operations was not yet great, but Dr. Chadwick thought there was no question that the removal of the whole of a cancerous growth does prolong the life at least and in some cases give perfect exemption from recurrence of the disease. As Dr. Baker's operation involves an opening of the peritoneal cavity, the danger of the operation must be nearly as great as that from the total extirpation of the uterus, by Freund's abdominal or by Schroeder's vaginal methods, with the results of which operations Dr. Baker's results must consequently be compared. The protection from a recurrence of the disease can hardly be claimed to be as likely as by these methods. While theoretically Dr. Baker demonstrates a removal of the entire disease, practically this success must be problematical in almost every instance, owing to the difficulty of distinguishing sound from diseased tissues during such an operation. His results are, however, good.

DR. BAKER referred to a case which he had seen with Dr. Brown, of Stoneham, three years ago. In this instance the uterus was fixed, and with this condition he would not operate for entire removal. As to the spoon and caustics these would not be considered sufficient in the case of an open ulcerating cancer of a movable breast, and he would consider it unwise to use that method in a like condition of the uterus. It would be better to remove the whole disease, keeping within healthy tissue throughout the operation. Caustics, moreover, require more dressings, and are more apt to cause constriction of the vagina than the thermo-cautery. In cases in which the disease was constitutional from the start Dr. Baker said he would operate to relieve hemorrhage or prevent sloughing.

DR. FIFIELD avowed that it was impossible to discriminate between cases with and without cachexia. The surgeon, he said, who sees cancer in other parts does not judge the case from the general appearance. How often the skillful removal of a diseased breast is followed by disease elsewhere! When the breast or the testicle is cancerous it is cut out, and it would be better in like manner for like reason to cut out the whole uterus.

DR. W. SYMINGTON BROWN, of Stoneham, said that he had operated a great many times for cancer of the breast, and but once successfully as regards recurrence. He was inclined to think that the disease, cancer, was at first local, but soon constitutional. He remarked that all cancerous disease, especially that of the uterus,

was attended with a great deal of discomfort, and that it was a duty to remove the cause of the discomfort or the offense. Dr. Brown mentioned a case of cancer of the face in which the actual cautery, used on four different occasions, gave his patient great relief from pain and nervous irritation. In a case of cancer of the vagina, removed about eighteen months ago, the disease returned in six months; the patient was operated on a second time by Dr. J. R. Chadwick, and the actual cautery freely applied. The disease appeared again within six months, and the patient died two months later.

DR. LYMAN said he agreed with Dr. Brown; that it was desirable to operate to arrest pain, hemorrhage, odor, etc. He thought it the better plan to remove the whole uterus, as with a less radical operation one did not know when the disease was wholly included in the removal. For partial purposes he preferred the curette and the subsulphate of iron. He did not, however, believe in the radical cure of the disease, and in a case living ten years after the operation he should be very much inclined to doubt the diagnosis. He considered it the imperative duty of the physician to repair lacerations of the cervix, under the belief, now so generally entertained, that these, subject as they are to constant irritation, are a hot-bed for malignant growths. Dr. Lyman remarked upon the slowness of progress of many cases of uterine cancer, and instanced a case in a lady seventy years old. The disease, which was diagnosed in Paris, between five and six years ago and fully confirmed here, has during the last four years made but trifling progress.

In answer to a question by Dr. Reynolds, as to breach of cervical continuity as evidence of foregoing childbearing, Dr. LYMAN said that no other cause being given, such conditions of the cervix were, to his mind, a strong proof of previous labor. On the other hand, the absence of any such lesion was no proof that the woman had not been delivered, and instanced a case now in the hospital in which the external os was round, small, and perfectly intact, and the fourchette also unruptured, although the woman had given birth to a child at full term. He had shown the case to the students as important in a medico-legal point of view.

#### OBSTINATE VOMITING OF PREGNANCY.

DR. FIFIELD said that for several years he had prided himself on being able to subdue this symptom either by the administration of the bromide of potassium or by the injection of chloral hydrate, one half drachm, into the rectum. These had never failed him till about a week before the meeting, when the case of a woman, three or four weeks pregnant, fell into his hands. She had been vomiting for several weeks before he saw her, and then was rejecting everything. Dr. Fifield first tried the bromide, then the chloral, with the simplest diet, then ingluvin, ten grains at five or six A. M., fifteen at nine o'clock, iced milk bubbled with water from the siphon, and a slice of bread; the second morning the same plan, the third day three grains three times, as directed by an English gynecologist. Meanwhile, so far from amending the patient got into an alarming state, and began to vomit blood. On the morning of the day before the meeting Dr. Fifield applied Sims's speculum, drew down the cervix, a little excoriated, and covered it thoroughly with nitrate of silver. He then ordered bromide of potassium,

ten grains, every two hours. The next day she was well.

DR. BLAKE remarked that the most obstinate cases of vomiting in pregnancy had been associated with abrasions of the cervix.

DR. BENJAMIN CUSHING said he had seen in his own practice of twenty-eight years two cases only which threatened a fatal termination. In the first case the patient seemed in danger of starvation, she also had convulsions. Dr. Cushing gave as the last, and apparently effectual, remedy fifteen drops of Smith and Melvin's elixir of opium, twenty minutes before each meal. The vomiting ceased, and the patient went her full time. In the second case all remedies taken internally failed. The os uteri was dilated with sponge-tent, miscarriage followed, and the patient recovered.

Another case was mentioned where long, obstinate vomiting, not due to pregnancy, was followed by relief on using suppositories of sulphate of morphia. One quarter of a grain was given at bedtime for a few nights, and then the quantity gradually diminished. The morphia was used for about three weeks.

DR. W. SYMINGTON BROWN remarked that he had seen two fatal cases of the vomiting of pregnancy, one of which was reported in the *Journal of the Gynecological Society of Boston*, Vol. II., p. 208. The other occurred in the practice of the late Dr. Wm. F. Stevens. Abortion was induced by means of a sponge-tent, but the patient died. The emesis was somewhat relieved by the operation.

DR. ABBOT had seen one fatal case, in which the most relief had been found from large doses of morphia and dilatation of the cervix. He called attention to the fact that abortion is not allowed the Catholic patient as a means of relief. The patient referred to belonged to that church.

DR. LYMAN referred to a severe case which was treated by Copeman's method; abortion accidentally ensued, and the patient got well.

#### PROCEEDINGS OF THE MONTHLY PHARMACEUTICAL MEETING OF THE MASSACHUSETTS COLLEGE OF PHARMACY.

B. F. DAVENPORT, M. D., REGISTRAR.

At the regular meeting of January 10, 1882, a paper by F. A. DAVIDSON, Ph. G., on Stearine and Stearic Acid, was read, calling the attention of pharmacists to commercial stearine, the by-product in the manufacture of lard oil and glycerine, at present used mainly in the manufacture of soap and a few mechanical applications, as a lubricant, and leather stuffer in the process of currying, and costing less than ten cents per pound. He recommends it as a cheap and useful base for ointments, especially for the many old "salves" that the pharmacist is often called on to dispense for veterinary use. As not requiring the addition of wax, it can replace the petroleum products in this class of preparations.

PROFESSOR MARKOE spoke of the fact of commercial lard being made not from the "leaves" alone, as in the Pharmacopœia, but the fat from the entire hog being thus rendered. That the Pharmacopœia rightly directs only that perfectly fresh and sweet should be

used, for that no manipulation can ever restore that which has become in any degree rancid.

MR. SHEPARD spoke of the fact of pharmaceutical preparations made up with the paraffine products not being so readily absorbed by the skin as those in which a fatty base was used.

MR. B. F. STACEY spoke of mutton tallow as being in common country domestic use found to be a most efficient emollient.

MR. G. F. DINSMORE explained his ingenious modification of the plaster machine, by which he is enabled to readily spread them of any desired size.

It was the opinion of several that there was at present a decided reaction in favor of the plasters of the Pharmacopœia over the proprietary article.

DR. DAVENPORT drew attention to the recent extensive and very valuable additions to the College library, the College now having in its library one of the most extensive collections of pharmaceutical literature in the country. It receives the current numbers of about every journal relating to pharmacy which is published in the English language. It has also the leading German and French publications, such as the *Archiv der Pharmacie* and the *Journal de Pharmacie et de Chimie*. Of the former of these, the most valuable of all those published, it has a complete file, and of the latter a set not fully complete, but which is expected to be so before long. The collection of the pharmacopœias of all nations, in all their various editions, is believed to be far beyond any rival anywhere in America, at the least.

— In regard to the Harvard Dental School, the Dean, Dr. Chandler, reports that the graduating class consisted of five, and adds:—

Attention has been frequently called to the pressing pecuniary needs of the School, and early in the year an attempt was made to obtain from the generously inclined of the community a small sum to enable the School to pay off its debt and obtain quarters in the new medical building now being erected. A committee was formed to solicit subscriptions, consisting of the professors and instructors of the School. These men, who were already giving about one twelfth of their working hours to the School without compensation, found it impossible to take more of their time from their business, and impracticable to accomplish anything by evening calls; therefore this subscription has practically dropped, and some other method must be adopted, if anything is to be accomplished in this direction. At the last meeting of the Alumni of the School, however, an attempt was made to interest the graduates of the School in the matter, and a paper was signed on the spot by thirteen of their number, agreeing to give to the fund one hundred dollars each in five years, or twenty dollars each year. This number has already been increased, and more will probably be added as their attention is called to the subject. If it were fairly understood by the community that not only a School of Dentistry, but a Dental Infirmary, averaging eight thousand cases each year, depended upon the gratuitous services of half a dozen men, any one or all of whom may at any moment grow weary of the burden imposed upon them, it does not seem that this condition of things would be allowed to continue.

# Medical and Surgical Journal.

THURSDAY, JANUARY 26, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

## THE RESULTS OF AN EXAMINATION MADE IN 1880 OF SEVERAL SEWERAGE WORKS IN EUROPE.

SOME eighteen months since the National Board of Health sent Mr. Rudolph Hering, of Philadelphia, in his capacity of civil and sanitary engineer, to examine and report upon several sewerage works in Europe. That gentleman's report to the Board has just been published as Supplement No. 16 to the Health Bulletin. It is a voluminous and carefully prepared document, whilst stating with conciseness, with fairness, and, in general, very clearly the objects to be sought in sewerage systems, the modifying influences of locality, the various systems at present in more or less successful operation, and the important questions of first cost and cost of maintenance. We shall give a brief abstract of some portions of this Supplement in the hope that some readers may be induced to read the original who otherwise might not do so, and that others may at least know where to find information in a convenient form, in regard to which physicians are liable at one time or another to be consulted.

After a short introduction Mr. Hering takes up general systems and their application; these fall under two heads, (1) dry removal by (a) disinfection, (b) casks and pails; (2) water-carriage or sewerage proper by (a) the combined system, (b) separate systems. The common cess-pit is not considered, as it, generally speaking, violates the sanitary requirements.

In the introduction reasons are given to account for the existing diversity of opinion regarding the best method of removing offal and waste-water from houses and towns, which gain the confidence of the reader, and show that the writer has investigated his subject in a judicial and broad spirit, and not as the advocate of any pet theory, although it is evident in the course of the report that where there are no exceptional local contra-indications he favors the combined system of water-carriage. In this question even more, perhaps, than in some others the habitual engagement of the mind in certain directions tends greatly to influence opinions, and to cause a professional bias. It was observed in Europe, as a rule, that chemists, physicians, and agriculturists are prominent among the opponents of the water-carriage system, their professional studies leading them to dwell upon the evils coincident to, though not inseparable from, sewers, as soil contamination, gases and germs, pollution of river and sub-soil water, the possible dangers of sewage farming, and the manurial value and economy of un-

diluted excreta; that engineers are quite generally in favor of water-carriage, though divided in their estimates of the combined and separate systems as their experience may have been gained in large cities or small towns. From these and other reasons the conclusion was reached that a careful inquiry into various points must be made before we can understand the numerous works and designs, and that we must be aware of the fact that some opinions are given from a sanitary point of view alone, others solely from financial considerations, or from conclusions gained in dissimilar localities to those in question.

The sewerage question must be treated from two aspects. As the works are to receive, convey, and discharge organic waste products, the decomposition of which is, either directly or indirectly, the cause of unhealthful influences, it is necessary to examine them first of all from a *sanitary* point of view. When a satisfactory standard in this direction can be reached, the next inquiry is into the expense attached to their execution, in other words, into the least possible *cost* at which a sanitary condition can be attained.

These two considerations alone decide their merits. It will be found that several of the systems, if properly designed, constructed, and maintained, will have no serious sanitary defects, and that their relative advantages will depend mainly on the question of cost. As the latter varies with the local conditions it is evident that these will almost wholly determine the selection of the system.

These points it is important to keep in view when trying to determine the relative value and applicability of the different methods and systems for the removal of excreta, waste and surface water.

(1.) *Dry Removal.* Among the methods for dry removal the only ones to be recommended from a sanitary point of view are disinfection and subsequent removal at convenient intervals, or storage in sealed casks or pails with removal at fixed intervals. Disinfection is accomplished by facilitating oxidation through the addition of porous materials, such as dry earth or charcoal, or by decomposition and the conversion of injurious into uninjurious compounds through the application of carbolic acid, chloride of lime, creosote, etc. The well-known earth closet is an example of the one kind of disinfection; the *fosse filtre* and *fosse mobile* of Paris, the *torne* of Germany, and the "pail" of England are examples of the other kind, the *fosse filtre*, however, being practically a transition stage between the common pail system (*fosse mobile*) and water-carriage, and is only practicable where some form of sewer exists.

The sanitary value of dry removal being determined, the form to be adopted would be influenced by financial considerations imposed by local conditions, though by all the forms mentioned a concentrated and valuable manure is produced.

To compare favorably with water-carriage the common "pail" system must be restricted to: (1) Small towns, on account of the expense of cartage; (2) Towns where the regular exchange of the pails can be enforced with almost military strictness, which is

seldom found outside of a few European countries; (3) Dwellings where water-closets cannot be used; (4) Localities where sewerage would be very expensive; and (5) Where the waste water can be led over the surface of the ground without causing offense.

From a purely sanitary point of view the "dry-earth closet" is preferable, but the supply and removal of the substance used as a disinfectant renders it slightly more expensive.

(2) *Sewerage Proper or Water-Carriage.* — A historical review of the development of sewerage from the time when the first sewers in the more modern European towns were obtained simply by arching over the natural water-ways, which had become fouled by general refuse continually cast into them, — their position along the valley lines requiring a size sufficient for the conveyance of storm-waters, — to the present day leads Mr. Hering to the statement, as a result of his inspection, that: —

The present time furnishes the engineer with enough experience and facilities to economically design, construct, and maintain sewerage works which can effectively satisfy the just demands of sanitarians. If this is to be the conclusion, it must on the other hand be based on the condition that engineers pay greater attention to these demands, and not ignore the fact that they are the *prior* claim which the works should satisfy.

Also for dwellings, where sanitary precautions are even more important than in the streets, water-closets are preferable to the best-managed dry closets, because a much greater degree of cleanliness can be attained. Therefore, if all other governing points are equal, water-carriage should always be recommended *versus* dry removal. But the rapid and continuous flow of water-carried sewage from its entrance into the sewers to its final outfall forms the chief claim of superiority over the dry removal.

The remaining point of comparison is the cost. It has already been stated under what circumstances dry removal will be most economical, which implies to a certain extent the conditions under which sewerage is to be preferred. These can now be directly stated as follows: —

(1) Where a regular water supply in sufficient quantities is furnished to the dwellings, this being the most essential condition.

(2) Where waste water is sufficiently abundant and foul, and therefore requires rapid removal to a distant point, which will usually follow the former condition, especially in large towns.

(3) Where the population is dense, which relatively decreases the expense per inhabitant.

(4) Where the topographical features and location of the town do not require an unreasonable outlay of money. Water-carriage would, for instance, not be economical in small towns, on very steep and irregular slopes, with bed-rock near the surface, or where the site is a long, narrow strip along the shore of a large river, when the expense of sewerage would be out of proportion to its benefits over the dry removal.

(5) Where the disposal of sewerage offers no great difficulties or expense. It is questionable, for

instance, whether sewerage could be advised for an inland town having a very cold climate and where, from the absence of a large river, its sewerage must be purified.

(6.) Finally, in general, where the interest of the amount invested in sewerage will be smaller than the cost of dry removal, provided the latter is kept up to a sanitary standard. This condition will cause the advantages of water-carriage to increase with the size of the cities, but the exact point beyond which sewerage is cheaper than dry removal can only be determined from the local peculiarities.

A water-carriage or sewerage system of removal being determined upon for any locality a selection must be made between the "combined" and "separate" systems, or some compromise between the two. The combined system may be roughly described as serving the double purpose of removing sewage and rain-water by means of the same sewers; the separate system is the separation of sewage from rain-water and their removal by different channels, and originated from causes mainly financial. As modifications of the separate system the report mentions the Shone system, proposed by Mr. Shone, of Wrexham, England, and the Liernur system, proposed by Captain Liernur, of Holland. The Shone system, which is as yet on trial on a small scale only, is intended for localities where, for some reason, sewerage requires a frequent lifting. Self-acting sewage ejectors are distributed over the district and operated by compressed air supplied from a central station. The sewage runs into an iron container, holding from one to two cubic yards, and is then automatically ejected and lifted to any desired height. The advantage of this class of pumps consists in lifting small quantities at any number of convenient points, so that it can continue its course each time in shallower sewers and with better gradients. The economy and convenience of compressed air for transmitting power to long distances, in comparison with steam, makes the principle a practical one.

The Liernur system evidently had its origin in the cess-pool system, and is practically an extension of the vacuum cylinder used to evacuate the contents of water-tight pits, notably in Paris. In its original form it should hardly be classed under water-carriage systems, and even now the matter which it is intended to remove is rather suspended in water than carried by it. Yet the character of the sewage and the entire works themselves are so similar to what is given under this head that an absolute distinction is not warranted.

The present system, as used in four or five towns in Holland, may be briefly described as follows: The excreta drop into an ordinary hopper-closet, which is ventilated from its upper edge by a pipe leading to the roof. Water is permitted for flushing, although there are restrictions as to its quantity. Under the closet is a trap from which the matter drops into a vertical soil-pipe, and then passes horizontally to the "barometrical" trap and on to the street mains. These unite in an underground iron reservoir, sufficiently large to hold the excrements from the number of buildings in connection with it, and provided with

necessary stops and valves. From here a delivery-pipe leads directly to the central station where the air pump is situated, and where the sewage is run into barges and taken away to the place of final disposal.

The combined and "separate" systems of removal with their modifications being shown, when properly executed, to satisfy sanitary requirements in the abstract, the factor which will mainly govern a preference is less the sanitary value, as frequently asserted, than the cost of construction and maintenance. But as also the cost depends on the locality, on its physical features, on social requirements, and on the value of ground and materials, it is evident that the criterion for judging the relative advantages of the different systems, both from a sanitary and financial point of view, is the locality itself. And as the conditions presented by the various cities and places are exceedingly different, not one particular system will be the best for all localities, but different external conditions will demand as radically different solutions, both in general and detail.

This division of the report, therefore, concludes with a brief recapitulation, which, from its importance and clear conciseness, we give entire, of the principal local conditions under which each of the water-carriage systems seemed to be best applicable, as far as it is possible to judge from a general point of view. In some cases it may require the closest local examination, however, to determine a preference.

The combined system is suitable —

Where rain-water must be carried off under ground from extensive districts, especially when they are closely built up, as in large cities, and where new sewers must be built for this purpose.

Where purification is not required or is not difficult, and storm-water overflows are not objectionable in polluting the streams.

Where a sufficient amount of water or sewage is available for flushing the larger sewers.

The best examples were found in Frankfurt, London, Hamburg, Brighton, Liverpool, Berlin, and other towns.

The separate system is suitable —

Where rain-water does not require extensive underground removal, and can be concentrated in a few channels slightly below the surface, or where it can safely be made to flow off entirely on the surface. Such conditions are found in rural districts where the population is scattered, on small or at least short drainage areas, and on steep slopes or side-hills.

Where an existing system of old sewers, which cannot be made available for the proper conveyance of sewage, can yet be used for storm-water removal.

Where purification is expensive, and where the river or creek is so small that even diluted sewage from storm-water overflows would become objectionable, especially when the water is to be used for domestic purposes at no great distance below the town.

Where pumping of the sewage is found too expensive to admit of the increased quantity from intercepting sewers during rains, which can occur in very low and flat districts.

Where it is necessary to build a system of sewers for house drainage, with the least cost and delay, and the underground rain-water removal, if at all necessary, can be postponed.

Under such conditions the ordinary separate system can generally be applicable, yet certain special features of the locality may determine in favor of Shone's system; for instance: —

Where pumping of the sewage to moderate elevations is advantageous or required at several or numerous points not greatly distant from each other, in order to increase the grade and velocity between them.

Where deep excavation is very expensive, either from being under the level of subsoil water or in rock, and where shallower sewers with better grades and intermediate lifts could be substituted, as in undulating grounds with rock near the surface when

the sewage is to be carried across the ridges, or in low-lying and very flat districts with excavations under water.

Finally, in mentioning the applicability of Liernur's system, it must be added that it is extremely doubtful whether it can compete with the other systems in any locality. The most favorable conditions are: —

Where the district is flat and low-lying, where a sufficient gradient cannot be had for a gravity flow, and where ordinary sewers are for some reason or other not expedient.

Good examples of the ordinary separate system are found at Oxford, Reading, Tottenham, and other small English towns. The best works on the Liernur plan are at Amsterdam. The Shone system has not yet been applied, except at Wrexham for trial purposes.

In conclusion, it may be said that as quite different conditions may occur in the same town, it is possible and practicable to adopt several systems for it. It may be found expedient to exclude rain-water from certain areas, whereas the combined system would be advisable in others.

The rest of Mr. Hering's report is occupied with  
III. Designs and Construction of Sewerage Works.  
IV. Maintenance of Sewerage Works. V. Cost of Sewerage Works. VI. Disposal of Sewerage.

In regard to the disposal of sewage the following conclusions are stated as those to which the opinions of authorities engaged with the subject converge and which the writer's personal inspection of the various methods and works warrant.

(1.) The expectations entertained for a long time that town sewage could be converted into a valuable manure, which would not only pay for the conversion but render it profitable besides, have been given up, save by a few parties interested in patent processes. The general opinion held at present is that sewage must, beyond all other considerations, be disposed of in a way which is least injurious to the community, that pecuniary profit cannot be looked for in every case, and that essential differences in topographical, physical, and geological conditions will require essentially different modes of treatment.

(2.) When sewage can be safely discharged into a large river or the sea this will generally be the most satisfactory and economical mode of disposing of it. This method is practiced in London, Vienna, Liverpool, Hamburg, and a large number of sea-coast towns, without presenting any objectionable features, care being taken that the sewage is not brought back to the towns by currents or winds.

(3.) When sewage must be purified before it is discharged into a stream, the most satisfactory method is by means of *irrigation*, provided a sufficient amount of suitable territory and soil can be had at the price of good farming country.

(4.) When sufficient land cannot be had for irrigation, on account of expense, etc., or during the winter months, when vegetation cannot absorb the sewage, *filtration* is sufficiently effective to purify it. During the winter it may be constantly applied; during the summer it should be intermittent. Examples are found at Kendal, Merthyr-Tydvil, and Abingdon, in England, and in the winter basins at Berlin.

The ground for this purpose must be a free soil, and the areas level, to allow the sewage to stand and gradually soak away. Here, too, the entire ground must be deep-drained.

(5.) Where land is not suitable for irrigation or filtration, or where none can be had on account of topo-

graphical conditions or expense, sewage can be purified by means of *precipitation* with sulphate of alumina or milk of lime, with subsequent filtration on a very small area, through prepared basins if possible.

(6.) It may finally be said that an absolute standard of purity for the effluent should not be given, but that its degree should depend on local conditions, on the size of the sewer, on the use to which its water is thereafter to be put, and on the distance from the next town. In many cases it will even suffice to purify only a portion of the entire sewage of a town, the rest not being considered objectionable in the river. Although the cost of sewage purification is greatly modified by local conditions, it will be found in general to increase as land becomes less available, or in the order given above. As the expense of land near a city generally increases in proportion to the size of the latter, the cost of purification per head of population will, *ceteris paribus*, be more expensive for large towns than for small ones.

The remainder of this excellent document of fifty-four pages is occupied by three appendices, No. 1 giving a tabular arrangement of data for eleven cities, No. 2 maximum rainfalls, No. 3 a catalogue of the literature on sewerage.

We have confined our too brief abstract to the portions of the report most nearly concerning the medical profession and sanitarians, namely, the general systems and their application, and the disposal of sewage. The other divisions, though no less admirably treated, are more especially devoted to the work of the civil engineer.

Mr. Hering deserves much praise for the manner in which his work has been executed, and credit is due the National Board of Health for making accessible to the public in so clear, concise, and reliable a form such valuable and much needed information on a very vital subject, the importance of which is yearly increasing with the growth in size and numbers of our American cities and towns.

#### VACCINATION IN BOSTON.

THE daily press is recording the outbreak of small-pox in various sections of the country, and its rapid spread in those cities and towns in which it has once fairly obtained a foothold. During the past year numerous cases have occurred in Boston, but, owing to the efficiency of the Board of Health, the prompt removal of the patient to the Small-Pox Hospital has prevented the disease from assuming an epidemic form. It is now more than ten years since the Massachusetts State Board of Health addressed a circular to the mayors of cities and the selectmen of towns in the Commonwealth, urging the importance of protecting the people by careful vaccination before small-pox, which was then, as now, threatening to revisit us, should appear.

Realizing the importance of early adopting prophylactic measures to prevent the occurrence of an epidemic of the disease in this city, the Board of Health has issued a circular, which we print elsewhere, call-

ing upon the citizens to see to it that they and those under their care are properly vaccinated. In spite of all the efforts of its opponents no unprejudiced person to-day doubts the efficacy of vaccination as a preventive against the spreading of small-pox.

It is to be hoped that the profession will use their best efforts in aiding the Board of Health in their endeavors to prevent the recurrence of an epidemic such as visited the city some years since.

#### VACCINATION: PRINCIPLES OBSTA.

SUBSEQUENT events, we think, have amply shown that the JOURNAL was neither too prompt nor too emphatic a year ago in calling the attention of the profession to the many indications that another outbreak of small-pox was probably at hand. An editorial of February 10, 1881, began with these words: "Our readers are doubtless aware by this time of the many indications that another outbreak of small-pox may be at hand. The last epidemic subsided early in 1871, after a duration of two years, in the course of which the disease proved fatal to 1040 persons in Boston. Since then we have enjoyed an unusually long period of immunity, extending over seven years. The disease is now, however, awaking from its long slumber, and, like a giant refreshed, is ready to renew its onslaught. From Europe, where it has prevailed during the past year, it has reached this country, and has established a foothold in several of our great cities of the Atlantic coast."

This same editorial ended thus: "Let our motto be *principiis obsta*; the means of resistance, vaccination, isolation, and revaccination."

There was, perhaps, a little disposition to criticise us at the time as alarmists and borrowers of trouble. But when it is remembered that since then New York, Philadelphia, Baltimore, Pittsburg, Cincinnati, St. Louis, Chicago, and the towns and States of the Northwest have suffered, some of them very severely, and all far more than Boston, from small-pox, we cannot but feel that the agitation of this subject, which the JOURNAL started last winter, has been sufficiently justified. In saying this we do not wish to be understood as under-estimating the value of the vigilance, efficiency, and discretion of the Boston Board of Health, but non-official activity is often desirable at a stage of events where official action or expression would be indiscreet. There can be little question but that vaccination and revaccination were practiced more promptly and more generally in Boston than elsewhere, and it is certainly to be hoped that a further continuance of this voluntary submission, which depends much upon the urgency of individual physicians, will avoid the necessity for the expensive and unpleasant machinery of compulsory vaccination as well as any remaining danger of an outbreak of small-pox in this neighborhood. Circulars which we are frequently receiving from State and city boards of health near by and at a distance—the last being from New Hampshire—show that all are now fully awake to these dangers and to the importance of prophylaxis.

## MEDICAL NOTES.

— The Royal College of Surgeons of England has voted to contribute twenty-five dollars to the guarantee fund of the Index Medicus.

— The late empress of China having recovered from her former serious illness, some half a dozen surgeons, chosen by governors of provinces, and sent to Peking according to imperial instructions to attend upon her majesty, have been rewarded by various appointments. One, it is announced, is to be made a taotai, or intendant of circuit, another a prefect, another a district magistrate, and so forth. "This," says the *Shanghai Courier*, "is very much as if, after the recovery of the Prince of Wales from his historic illness, Sir William Jenner had been made a county court judge, and Sir W. Gull a stipendiary magistrate."

— The Linacre professorship of physiology at Oxford, vacant by the death of the late Professor Rolleston, has been filled by the appointment of Mr. H. N. Moseley, M. A., F. R. S., Fellow of Exeter College and Assistant Registrar of the University of London. Mr. Moseley is well known as a comparative anatomist, and more especially for his good work as a naturalist of the Challenger expedition. The University of Oxford has made a good choice in selecting him from the several candidates. As Professor Rolleston laid the foundation of biological knowledge in Oxford, so his successor will have to build the superstructure. Biology has made such strides during the last twenty years that no single professor can again hope to occupy Professor Rolleston's unique position. Anatomy and physiology have to a large extent been divorced from each other, and separate teachers for each of these great divisions of science must be appointed at every university and college in which they are expected to make their special lessons and teachings manifest. The new régime in science at Oxford which must shortly come will have to take into consideration these developments of modern biological research.

Those of the readers of the JOURNAL who knew Mr. Moseley in Vienna will read with pleasure the above extract from a London letter to the *American Practitioner*.

— Professor Freund, of Strasburg, is reported to have been offered and to have accepted the chair of Obstetrics in Breslau, formerly occupied by the late Professor Spiegelberg.

## Miscellany.

## ALBUMINURIA IN PREGNANCY.

MR. EDITOR, — While albuminuria, especially when in connection with other symptoms of diseased kidney, is, in pregnant women, apt to be accompanied by convulsions, yet it is not always so. Until the subject shall be better understood the report of individual cases may be of use.

In the following case the urine of a primipara was examined July 15th, early in the ninth month, purely as a matter of routine, her condition being good. It contained a trace of albumen and a few epithelial casts.

August 1st. Feet much swollen. Finger rings a

little tight. Urine contained one eighth albumen and numerous epithelial casts.

August 12th. Delivered in about four hours from the first serious pains, the only thing worth noting being the force and frequency of the pains. Urine, drawn by catheter some hours later, contained one fifth albumen and many epithelial and granular casts. There was no milk, but nothing else to note for a week, the patient having been drinking freely of cream-of-tartar water since the swelling began. August 21st there was for the first time headache and diminution of urine, with a pulse of 110. The cream of tartar was increased, and one dose of spirits of nitrous ether given, when these symptoms disappeared.

There has been no other symptom referable to the kidneys. The urine has been of sufficient quantity, but was not examined until January 18th, owing to the absence of the patient for much of the time. It then contained neither albumen nor casts.

EDWARD M. BUCKINGHAM.

Boston, January 20, 1882.

## PREPARATORY MEDICAL EDUCATION.

MR. EDITOR, — I was much interested in the article by Dr. C. S. Minot, printed in a recent number of the JOURNAL.<sup>1</sup> The ideas advanced by Dr. Minot may seem novel, but doubtless many of them in a slightly modified form would be cordially endorsed by all advanced medical educators. It would seem that no one at all imbued with the scientific spirit can deny that a thorough, practical knowledge of biology is the best possible introduction to a course of medical study, but it seems too much to require medical schools to furnish instruction in general biology. A knowledge of general biology, as well as general chemistry and physics, ought to be made a requirement for admission to a medical school. A medical student should be well versed in these sciences, but their study ought to be made a part of his preparatory course. There would seem to be no more reason for reckoning general chemistry a branch of medicine than physics or botany.

Professor Huxley, in his discourse at the opening of the Johns Hopkins University, Baltimore, in 1876, made some extremely logical remarks upon this subject. He believes that a medical school has no right to include any of the fundamental sciences or branches of natural history in its curriculum. But we know that Huxley would be the last man to discourage the study of biology in its proper place.

Dr. Minot's arrangement of studies for first-year medical students would double the amount of work now required of them, which is already amply sufficient to engross all the time, and to tax the best powers of the most capable students.

In the writer's opinion a certain amount of attainment in biology, physics, and chemistry should be made a requisite for admission to the Harvard Medical School. Students who come unprepared in these subjects should be required to pursue courses of study at Cambridge until they have made good their deficiencies.

The institution in this country which has laid the most stress upon the need of a special preparatory course for the study of medicine is the Johns Hopkins University. Here a course, admirable in plan, is given

<sup>1</sup> A Grave Defect in our Medical Education, Boston Medical and Surgical Journal, December 15, 1881.

under the direction of Dr. Martin and others, which is fully described by Dr. Martin in his address at the opening of the biological department of the university, which was published in the *Popular Science Monthly* for January, 1877.

Besides an acquaintance with general biology, it is very desirable that students commencing the course at the Harvard Medical School should have an elementary knowledge of human anatomy and physiology. Such a knowledge could be obtained by the careful study of such works as Huxley's *Physiology*, Mivart's *Elementary Anatomy*, or Martin's *Human Body*. With such a preparation the student would be in a condition to better comprehend and retain the lectures on those subjects which it would be his privilege to listen to in the school. It is only by constant review, constant revolving around the subject in wider and more comprehensive circles, that we are enabled to grasp and firmly retain the slippery details of anatomy and physiology. Yours truly,

FRED. W. ELLIS, M. D.

MONSON, MASS., January 16, 1882.

EXTRACT FROM DR. EDWARD REYNOLDS' ADDRESS AT THE DEDICATION OF THE MASSACHUSETTS CHARITABLE EYE AND EAR INFIRMARY, 1850.

THE following extract from the address delivered at the dedication of the present building of the Massachusetts Charitable Eye and Ear Infirmary in 1850, by the late venerable Dr. Edward Reynolds, will have an interest for some of the readers of the JOURNAL.

As the London Eye Infirmary owes its origin to the Institution at Vienna, so the Massachusetts Infirmary, where we are this day assembled, must claim its parentage from that. The valuable work of Saunders, published in 1816, and the occasional reports of the Infirmary of which it was the first-fruits, began to excite a spirit of inquiry among several eminent individuals in our country. But no general movement was made in its favor until 1821, when the first eye infirmary in America was established by Dr. John Kearney Rodgers and Dr. Edward Delafield, two of the most distinguished physicians and surgeons in New York, who may be called the fathers of American ophthalmology. Filled with the spirit first received at the London institution, and finding on their return from Europe a great number of poor people afflicted with diseases of the eyes, they were desirous of extending a similar blessing to their native city. Accordingly, at the request of several of the senior members of the profession, they founded the New York Eye Infirmary, where they have ever since labored with praiseworthy diligence, devoting to its interests a great amount of time, that was with difficulty spared from other professional pursuits, uncheered by any adequate patronage of the public, though thirty-six thousand fellow-beings have received the blessings of sight and hearing at their hands, and reaping no other reward than the happiness of doing good.

"Two years after, in the latter part of 1824, the example was followed in Boston, and the first effort made whose noble result we are this day assembled to celebrate. Perhaps on this occasion I may be pardoned in saying that the Massachusetts Charitable Eye Infirmary partly originated in the fact that one of its

founders had the happiness of restoring a beloved father<sup>1</sup> to sight by the operation for cataract. The tender relation in this case of surgeon and patient, becoming extensively known among the small population then composing our community, brought to his observation a large number of ophthalmic patients, and soon revealed the fact that the poor and laboring classes are peculiarly liable to these diseases, a fact now familiar to every one acquainted with the results of these institutions. Whoever would study the diseases of the eyes must pass by the houses of the affluent and enter those of the poor. The great majority of all these cases belong to the humbler ranks of society, and have their prolific parentage in the various privations and sorrows unavoidably consequent upon poverty."

A TEST CASE ON SKIM MILK.

WE have already noticed in our columns the attempt which was to have been made in this city to sell skimmed milk and the probable action of the Health Board.

It appears that a case has already come up, and, as was inevitable, was taken into the courts for settlement. Ten cans of skimmed milk were offered for sale at three cents per quart, but the entire lot was seized by the Inspectors of the Board, and action commenced against the offender.

The case is one of unusual interest and importance as being the first of an organized movement to sell skimmed milk under its true name.

The Board based the prosecution on the ground that such milk is an adulterated and unwholesome article of diet, and that the sale of it is in violation both of the city sanitary code and the State law against adulteration.

The defense held that the article in question could not be called "adulterated," and that the law prohibiting its sale was unconstitutional. As to the former point it seems clear that it is an adulterated article according to the meaning of the State law, for in Section 3 of said law we read: "An article shall be deemed to be adulterated within the meaning of this act;" "b. In the case of food or drink;" "3. If any valuable constituent of the article has been wholly or in part removed."

As to its constitutionality, that is a matter for the courts to decide. But in the present case, in charging the jury, the Recorder said he should uphold the constitutionality of the law. He said also that in view of the importance of the case he should require the jury to hand in a special verdict consisting of answers to four questions propounded by the court. The answers to these questions were subscribed to by every member of the jury. By this special verdict the jury found that the defendant exposed for sale "impure, adulterated, and unwholesome milk;" that the milk had not been "watered, or adulterated, reduced, or changed in any respect other than by the removal of the cream therefrom," but "that milk which has been reduced by the removal of the cream therefrom" is "both injurious and unwholesome."

The case will, of course, be carried up to the Supreme Court and the Court of Appeals, but the Board's attorney thinks the result will not be changed.

<sup>1</sup> Edward Reynolds, Esq.

The Board is to be congratulated on this its first victory in the attempt to suppress so great an evil. Probably few people outside the medical profession realize the danger and harm that must result from the unrestricted sale of this article. Milk has been, and will continue to be, the chief article of infant diet, and for this use above all others it should be in its pure and natural form. Not only are the poor tempted to buy the inferior article from its lower price, but they often get the cheaper while paying for the better kind, by calling indiscriminately for "milk," and not knowing or not noticing the difference.

For the sake of the multitude of helpless poor, we wish the Board continued success in its good work in this direction.

The experience of New Jersey goes to show that a law permitting the sale of skimmed milk, as such, does not protect the public. The New Jersey law permits the sale of skimmed milk, provided the can has a label stating the fact that the milk is skimmed soldered on the side. This label is small, and very rarely noticed by the public, as the can is usually either set in the ice-box of the retail dealer's store, or is carried about in the milk dealer's wagon. The milk is not sold as skim milk, but for whatever a customer asks. The conclusion of the New Jersey authorities, therefore, is that just so long as skim milk is allowed to be sold will fraud be practiced.

In this connection we may refer to the condemnation recently, at Camden, of eight hundred quarts of skim milk by the State Inspector, Dr. Newton. We understand that \$1,500 has been raised to be applied toward securing the repeal of the New Jersey law. We hope the common sense of New Jersey legislators will oppose any scheme to abolish a law which has been of the greatest benefit to the agricultural community as well as to the public who buy; protecting them from fraudulent dealers, and securing for the honest dairyman a better price, and giving him an equal chance with the man who prefers to skim and water. — *Sanitary Engineer*.

## THERAPEUTIC NOTES.

### IODOFORM AS A DRESSING FOR WOUNDS.

Mikulicz (in *Wiener Med. Wochenschrift*, 1881, No. 23) gives results of the use of iodoform in Billroth's wards. He claims that it is in antiseptic qualities equal to carbolic acid, is more easily used, and less apt to cause constitutional disturbance by absorption. Symptoms of poisoning are, however, seen in rare cases, and in the *Deutsche Med. Woch.*, 1881, No. 34, A. Henry describes two fatal cases. (See page 460 of last volume of this journal.) The symptoms are of the narcotico-irritant type.

In open wounds the iodoform is sprinkled on the surface and covered with lint and gutta-percha tissue, fixed by a bandage. The results have been very satisfactory; the dressings require changing but seldom, discharge is slight, decomposition never occurs, and there is rapid formation of healthy granulations. In incised wounds healing is even more certain than with carbolic acid, and there is much less fear of absorption causing constitutional disturbance.

Wounds implicating mucous surfaces, as of the mouth or rectum, are usually very difficult to treat an-

tiseptically. In such cases iodoform, applied on gauze compresses, has been found to completely prevent offensive smell, and to cause no discomfort to the patients.

In a case of removal of an abdominal tumor iodoform was sprinkled into the cavity, and the wound closed at once. The patient recovered without a bad symptom.

In septic, gangrenous, or sloughing wounds the results were especially satisfactory. Sprinkling with iodoform removed all smell in from four to six hours, and the wounds healed rapidly and without discharge, even in some cases where severe constitutional symptoms had already appeared.

In strumous diseases iodoform is said to give such brilliant results as almost to entitle it to the rank of a specific. (See also V. Mosetig-Moorhof in *Wien. Med. Woch.*, 1881, No. 13.) Fungating ulcers with spreading undermined edges and offensive discharge healed rapidly and completely under a thick layer of iodoform.

In lupus also its effects are gratifying. Riehl (*Wien. Med. Woch.*, 1881, No. 19) gives the results of twenty cases in Kaposi's clinique. The epidermis, when necessary, having been removed by the application of five to ten per cent. solution of caustic potash, the iodoform is laid on in a layer several millimetres thick, and fixed as above described. On removal of the dressings in from three to eight days the disease is found completely removed, redness and swelling gone, and the sore skinned over.

In deep wounds, when the powder would be difficult to apply, Mikulicz recommends pencils composed of one part of iodoform to two of cacao butter, and for injection a twenty per cent. ethereal solution. The smell of the drug can be overcome by adding one minim bergamot to ten grains of the iodoform, or moistening with an ethereal or alcoholic extract of Tonquin bean. Local irritation can be effectually prevented by previously oiling the sound skin near where the iodoform is to be applied. — *Centrbl. f. Chir.*, 1881, Nos. 32 and 39.

### IODOFORM SUBCUTANEOUSLY IN SYPHILIS.

Dr. E. Thomann, of Graz, has treated a series of cases of recent syphilis with well-marked skin manifestations and glandular enlargements by the administration of iodoform subcutaneously, and states that even after ten to twelve injections great improvement in all the symptoms is manifest. The preparation he used consisted of 6 parts of iodoform suspended in 20 parts of glycerine; this was administered in doses of 0.3 gramme, increasing gradually to 0.75 gramme. No abscesses were produced, though the skin became slightly red and tender, and the spots operated on were harder than the surrounding parts, and slightly swollen for a few days. Iodine may be detected in the urine in two hours after the first injection; no smell of iodoform was perceptible either in the breath, perspiration, or urine. There was no constitutional disturbance or drowsiness, and the temperature and pulse were unaffected. A solution of iodoform in almond oil (0.3 gramme in 6 ccm.) was also tried, but proved too irritating; it caused an erysipelatous reddening of the skin. The feeling of local hardness was absent, however, as the oil was so much more quickly absorbed than the glycerine preparation. — *Chl. f. d. Med. Wiss.*, 29th October, 1881. — *Glasgow Medical Journal*.

## THE FINANCIAL CONDITION OF HARVARD COLLEGE.

The financial condition of Harvard College proper gives much concern to the Corporation, according to President Elliot, who says in his annual report: The withdrawal of nearly \$100,000 from the free capital in 1875-76, to pay for the extension of Gore Hall, the fall in the rate of interest on its invested funds (two per cent in seven years), and the heavy additional expenses which it has been yearly obliged to incur, taken in connection with the cessation since 1876-77 of the former rapid increase in the number of students, have occasioned three deficits within the past four years. These three deficits have taken from the free capital of the College nearly \$50,000. To be sure, no such loss would appear if the total capital of the College on September 1, 1877, were compared with the total capital on September 1, 1881; because in that interval new gifts of unrestricted funds have been received to an amount somewhat greater than \$50,000; but it remains strictly true, nevertheless, that the College has been living beyond its income for four years, to the average amount of \$12,500 a year. The deficit for 1880-81, amounting to \$34,469.19, is the largest which the College has ever incurred, and has forced the Corporation to consider anxiously the measures

necessary to prevent the recurrence of such a reduction of capital. After deducting from the deficit all those expenses of the year which can properly be called extraordinary, there remains an excess of current expenses over receipts to the amount of at least \$15,000. Since the beginning of the current year a gift of \$100,000, derived from the estate of the late Eben Wright, has been received from T. Jefferson Coolidge, Esq., who has directed that the income go towards the cost of administration and service in the Library. As the College bears the whole cost of carrying on the Library, this most timely gift will relieve the College by the whole amount of the income to be derived from it, namely, by \$1,000 a year from January 1, 1882. The Corporation will this year cut off certain expenses in the Library of recent origin, and charge their just proportion of the expenses of the Gymnasium and of clerk hire in the Bursar's office to the Divinity, Law, and Scientific Schools; and next year will in addition charge special fees for supplies to all students who work in laboratories, and abolish a few unimportant courses of instruction, the loss of which, they believe, will not be seriously felt. They see some reason to believe, moreover, that the number of students will next year increase. It will, however, be impossible to avoid a large deficit for the current year.

## REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 14, 1882.

| Cities.                            | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |                     |

Deaths reported 2172 (no reports from Philadelphia, Cincinnati, Chicago, New Orleans, and Nashville); 825 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 531, consumption 293, lung diseases 369, diphtheria and croup 175, scarlet fever 119, small-pox 42, typhoid fever 44, measles 36, diarrheal diseases 36, whooping-cough 22, malarial fevers 18, erysipelas 11, cerebro-spinal meningitis nine, puerperal fever nine. From *scarlet fever*, New York 68, Brooklyn 27, Buffalo 10, St. Louis and Baltimore four each, Boston and Worcester three each. From *small-pox*, Pittsburgh 24, New York 13, Boston two, District of Columbia, Milwaukee, and Holyoke one each. From *measles*, New York 28, Brooklyn four, Buffalo two, St. Louis and Pittsburgh one each. From *whooping-cough*, New York nine, Boston and Providence two each, Brooklyn, Baltimore, District of Columbia, Pittsburgh, Milwaukee, Cambridge, Fall River, Taunton, and North Adams one each. From *malarial fevers*, New York six, Brooklyn and St. Louis five each, District of Columbia two. From *erysipelas*, St. Louis four, Providence two, Brooklyn, Baltimore, Lynn, Salem, and Holyoke one each. From *cerebro-spinal meningitis*, New Haven three, New York two, Milwaukee, Charleston, Fall River, and Springfield one each. From *puerperal fever*, St. Louis and Milwaukee two each, New York, Brooklyn, Boston, Providence, and Fall River one each.

Ninety-one cases of small-pox were reported in Pittsburgh, 15 in St. Louis, seven in Holyoke, six in Brooklyn, three in Baltimore, Boston and Milwaukee one each; diphtheria 26 cases, scarlet fever 14, typhoid fever nine in Boston; diphtheria seven, scarlet fever seven, in Milwaukee.

In 34 cities and towns of Massachusetts, with a population of 1,016,433 (population of the State 1,783,086), the total death-rate for the week was 20.97, against 18.45 and 21.52 for the previous two weeks.

For the week ending December 10th, in 149 German cities and towns, with an estimated population of 7,936,736, the death-rate was 22.9. Deaths reported 3492; under five 1626; pulmonary consumption 437, acute diseases of the respiratory organs 279, diphtheria and croup 203, diarrheal diseases 117, scarlet fever 113, typhoid fever 52, whooping-cough 50, measles and röteln 45, puerperal fever 20, typhus fever (Thorn) three, small-pox (Aachen) one. The death-rates ranged from 11.4 in Bremen to 32.9 in Essen; Königsberg 24.7; Breslau 28.8; Munich 26.2; Dresden 24.6; Berlin 25.2; Leipzig 23.7; Hamburg 21.4; Hanover 24.1; Cologne 28.8; Frankfurt 16.7; Strasburg 23.1.

For the week ending December 17th, in the German cities

and towns, with an estimated population of 7,895,018, the death-rate was 24.3. Deaths reported 3682; under five, 1745; pulmonary consumption 538, acute diseases of the respiratory organs 304, diphtheria and croup 252, scarlet fever 106, diarrheal diseases 94, measles and röteln 67, whooping-cough 63, typhoid fever 47, puerperal fever 18, typhus fever (Thorn, Tilsit) two, small-pox (Aachen) one. The death-rates ranged from 11.9 in Bremen to 36 in Munster; Königsberg 28.4; Breslau 25.4; Munich 29.2; Dresden 21.7; Berlin 25.5; Leipzig 22.6; Hamburg 24.6; Hanover 25.8; Cologne 29.5; Frankfurt 16; Strasburg 19.7.

For the week ending December 24th, in the German cities and towns, with an estimated population of 7,697,184, the death-rate was 25.7. Deaths reported 3798; under five 1828; pulmonary consumption 513, acute diseases of the respiratory organs 375, diphtheria and croup 283, diarrheal diseases 101, scarlet fever 95, whooping-cough 67, measles and röteln 51, typhoid fever 51, puerperal fever 22, typhus fever (Thorn four, Memel) five, small-pox (Königsberg, Dresden, Aachen) three. The death-rates ranged from 15.6 in Mannheim to 38.3 in Chemnitz; Königsberg 32.8; Breslau 28.3; Munich 31; Dresden 28.1; Berlin 25.5; Leipzig 23.3; Hamburg 24.5; Hanover 22.4; Bremen 16.9; Cologne 26.2; Frankfurt 19.7; Strasburg 27.6.

For the week ending December 31st in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 27.3. Deaths reported 3976; acute diseases of the respiratory organs (London) 596, whooping-cough 181, measles 134, scarlet fever 126, fever 45, diphtheria 42, diarrhoea 34, small-pox (London 32) 34. The death-rates ranged from 16.9 in Bristol to 32.2 in Nottingham; Sheffield 22.1; Leeds 23.2; Birmingham 25.8; London 28.3; Manchester 29.8; Liverpool 31.9.

For the week ending December 17th, in the 21 chief towns of Switzerland, population 479,934, there were 28 deaths from acute diseases of respiratory organs, pulmonary consumption 25, diphtheria and croup 12, diarrheal diseases eight, typhoid fever and whooping-cough each four, small-pox, measles, and scarlet fever each one. The death-rates were, Geneva —; Zurich 25; Basle 24.3; Berne 21.1.

For the week ending December 24th, in the same towns, there were 41 deaths from acute diseases of the respiratory organs, pulmonary consumption 31, diarrheal diseases 22, diphtheria and croup 19, typhoid fever and scarlet fever each six, whooping-cough four, puerperal fever two, small-pox one. The death-rates were, Geneva 21.2; Zurich 26.4; Basle 25.1; Berne 46.8.

The meteorological record for the week ending January 14th, in Boston, was as follows:—

IGNORANCE AS A LEGAL EXCUSE FOR MALPRACTICE.<sup>1</sup>

BY A. E. PILLSBURY, ESQ.

It is not proposed to attempt in this brief paper an exhaustive examination of the subject indicated in the title, but only to glance at these interesting questions:—

I. How far can the ignorance of the physician be relied on in avoidance of criminal or civil liability for medical malpractice?

II. Does the law recognize any distinction, in respect of this liability, between different classes of practitioners?

A prosecution for malpractice, criminal or civil, ordinarily arises out of an offense of omission rather than commission; that is to say, out of the failure of the physician to apply due knowledge, skill, or diligence in his professional service. For positive misconduct, unwarranted by any claim or pretense of proper medical treatment, a physician undoubtedly may be liable to prosecution, as for assault or various kindred offenses, according to the facts. But with such cases, happily of rare occurrence, we have at present nothing to do. They fall into their proper divisions in the classification of the criminal law, and are not to be considered merely as cases of medical malpractice.

In England the extent of criminal liability for malpractice is settled by a long course of decisions.<sup>2</sup> It is there held that any person, learned or unlearned, who undertakes to deal with the life or health of another, is liable for manslaughter if the death of the patient results from his failure to use reasonable skill and diligence in his treatment. It seems, also, that he is there liable criminally, as for misdemeanor, for any injury to the patient caused by his default, though not resulting in loss of life.<sup>3</sup> It is true that a criminal intent is an essential element of all criminal offenses, but this intent may be inferred from the circumstances of the case; and the English courts will draw this inference, or allow it to be drawn by the jury, from evidence of reckless or grossly ignorant maltreatment, endangering health or life, without proof of any actual purpose of the accused to do harm to his patient.

In this Commonwealth a different rule prevails, and although the leading Massachusetts case has been directly followed in but few reported cases in other States, it is believed to have been generally acquiesced in, and to express a doctrine which is or is likely to be generally adopted in this country.<sup>4</sup> Samuel Thomson, whose name came to be bestowed upon the root-and-herb "school" of practitioners, was indicted in Essex in 1809 for the murder of Ezra Lovett, Jr., by giving him, on the ninth day of January, a poison called lobelia, of which he died the next day. The evidence showed that Thomson announced himself as a physician, and professed an ability to cure all fevers by means of his peculiar medicines, to which he gave various grotesque names not to be found in the Phar-

macopœia.<sup>5</sup> He was called as a physician to attend Lovett, who was suffering from a cold, and subjected him for nine days to a course of sweats, emetics, and purgatives, which at the end of that period resulted in violent convulsions, collapse, and death. The court (Chief Justice Parsons and Justices Sewall and Parker) observed that the prisoner's ignorance was very apparent, and that it did not seem to admit of any reasonable doubt that the deceased lost his life by the prisoner's unskillful treatment; but that there was no evidence of express malice, nor that the prisoner was regardless of his social duty and bent on mischief, from which, if proved, malice might be inferred; and therefore held that he could not be convicted of murder. The prosecuting officer thereupon urged that the prisoner was guilty of manslaughter, in rashly and presumptuously administering to the deceased a deleterious medicine, which in his hands, by reason of his gross ignorance, became a deadly poison. But the court unanimously held that if the prisoner, notwithstanding his ignorance, acted with an honest intention and expectation of curing the deceased by his treatment, he was not guilty of manslaughter, although death was the consequence, unless, however ignorant of medical science in general, he had such knowledge of the dangerous character of his remedy that the jury might reasonably presume its administration to have been the effect of obstinate and willful rashness, and not of an honest intention and expectation to cure. There being no evidence sufficient, in the opinion of the court, to support the latter theory, Thomson was acquitted.

In the light of this case it appears that one who deals with the sick cannot here be held to criminal liability except in case of wanton or reckless maltreatment, accompanied by knowledge of the probable consequences. Ignorance, however gross, exculpates him, if that alone occasions his default: not because ignorance is morally a justification or excuse of his conduct, but because it excludes the malice which is an essential ingredient of a crime. There is nothing in the case to show that the court made or admitted any distinction, in the application of the doctrine, between the learned and the unlearned, or between those who hold themselves out and publicly practice as physicians and those who make no profession of the art and no claim to the learning and skill required in its exercise. Thomson, to be sure, held himself out as a physician, and was shown to have commonly practiced as such, but no reason appears why the same rule should not have been applied to him had Lovett been the only patient he ever attempted to treat. Indeed, the reason of the rule applies with greater force to a person who undertakes to act as a physician only on a single occasion, and so far as they adopt it at all the courts will probably extend it alike to all persons employed for medical service, under whatever circumstances.

It would be useless to speculate upon the reasons which moved the court in Thomson's case to depart from the current of English authority. A sufficient reason, perhaps, is in the fact that upon sound and familiar principles of the law of homicide the decision seems to be a logical and necessary result from the circumstances shown in evidence. It is further countenanced by a *dictum* of Lord Chief Justice Hale, ap-

<sup>1</sup> Read before the Massachusetts Medico-Legal Society.

<sup>3</sup> 1 Bishop Criminal Law, 538.

<sup>4</sup> Commonwealth v. Thomson, 6 Mass. Reports, 134.

<sup>5</sup> One he called "well-my-gristle," another "ram-cats." It is not supposed that the profession will be able to identify them by this description.

parently founded on an obscure case in the Year-books, which the Massachusetts court cited with approval, but which has not been followed in the later English cases, that if a physician, whether licensed or not, give a person a potion without intent to do him bodily harm but to cure or prevent disease, and death results, it is no homicide. "I hold their opinion to be erroneous," adds the Lord Chief Justice, "that think if he be no licensed chirurgeon or physician that occasioneth this mischance that then it is felony, for physic and salves were before licensed physicians and chirurgeons: and therefore if they be not licensed according to the statute they are subject to the penalties in the statute; but God forbid that any mischance of this kind should make any person not licensed guilty of murder or manslaughter."<sup>1</sup> This view of the subject, characteristic of Sir Matthew Hale, though exceptional in his time and country, is more nearly conformable to general principles than the doctrine of the later cases. The existence of the English rule is probably due to the fact that it had become firmly established by a course of decisions before the humanitarian influences of modern times had begun to moderate the ancient rigor of the criminal law.

To educated physicians the American rule may appear to involve an unjust discrimination against themselves. Ignorance being held to excuse its own consequences, the more ignorant the practitioner the greater, apparently, his chance of escape; while the casual mistake or misfortune of the qualified physician is more likely to bring punishment upon him from the very fact of his education and the consequent increased difficulty of establishing to the satisfaction of the jury the theory of ignorance. But the rule of law applies with impartial benevolence to all, and the discrimination, if any, arises out of the facts. The law cannot be reproached that

"— where ignorance is bliss  
'Tis folly to be wise."

The extent of civil liability for malpractice, in respect of the persons against whom, and the circumstances under which, it arises, is less clearly defined in the books. The foundation of this liability is in the rule that he who offers his services to the public for employment in a special capacity is bound to possess and exercise a reasonable degree of the learning and skill ordinarily possessed by those who follow the same vocation in the same locality, and to use reasonable care and diligence in its application.<sup>2</sup> This rule is established in all countries where the common law prevails, and it affects all who profess any art requiring special skill or training. Professional persons are not held to insure the success of their efforts, nor to exercise the highest or even a high degree of skill; but they must be of average ability and diligence. Failing in this, they are answerable for resulting injuries. The principal issue of fact in actions for malpractice usually is whether the defendant has fulfilled these requirements. Under this rule it is obviously impossible for the ordinary physician to avoid liability if he fails in reasonable skill or care. Whether he be schooled or unschooled, "regular" or irregular, is immaterial. An action for malpractice may be maintained against him even if he be forbidden by express statute to practice medicine.<sup>3</sup> If he offers himself to the community as a

common practitioner he is held to guarantee his reasonable fitness for the business, within the limits above stated. The public profession of his calling forbids him to plead ignorance. He has thereby let the public to believe that he is reasonably well equipped for his work, and all who employ him have a right to rely upon his own representations.

But with reference to a class which hangs upon the outer verge of the medical profession, the inquiry is more difficult. There are in most communities, especially in great cities, numbers of persons—styling themselves clairvoyants, mesmerists, seers, *et id omne genus*—who do not profess to be physicians, who neither have nor pretend to have any professional knowledge or training, nor any scientific qualifications of whatever character for medical practice, who yet are constantly resorted to by multitudes of people for the treatment of disease. Beyond this, it occasionally happens that a person of another vocation, entirely unaccustomed to deal with the sick, is called to stand in the physician's place. It is said that a case of this character, in which a woman in labor lost her life under the hands of a shoemaker, acting for the nonce as accoucheur, is of recent occurrence in this city. Whether such persons can be held to civil liability for the consequences of their treatment, whatsoever they may be, must be considered still an open question. A hurried examination of the reports fails to disclose any direct adjudication of the point. Some light is reflected upon it from the circumstance that in many of the published cases the courts seem to rest upon the defendant's public offer of his services as a material element in the foundation of the action. The logical process which leads to a judgment against a physician for malpractice, when ignorance is relied on as an excuse, runs thus: (1) The plaintiff has been injured by the negligence or unskillfulness of the defendant; (2) the defendant says that he acted in good faith, and was ignorant of the patient's condition or the character of the remedy prescribed, etc.; (3) but he shall not now be heard to say he is ignorant, since he professed skill; (4) therefore he shall make good his default in damages. Obviously this argument does not apply to one who makes no profession of skill, nor of anything else except that he is a "clairvoyant" or what not. The common and public practitioner of medicine has undertaken to exercise skill, but this man has undertaken nothing save, perhaps, to do his best under the circumstances. If he does this, it is difficult to see how he can be held answerable for the consequences.

Another argument against his liability may possibly be drawn from the analogy between the action for malpractice and the ordinary action for negligence. The former rests upon the rule already stated, that he who professes especial skill must exercise it; the latter upon the rule or principle that every person shall so conduct himself as not to injure others. Between these rules there is a close relation, indeed; there is no essential difference between them, save that one is adapted only to particular cases, while the other is of general application to all the ordinary affairs of life. Ultimate analysis might show that the action for malpractice, unless founded in contract, rests alone upon the simple rule against negligence, modified to meet the special circumstances of the case. The essential elements of a cause of action for negligence are: (1) an injury to the plaintiff (2) resulting from the negligence of the defendant, (3) to which no negligence of

<sup>1</sup> 1 Hale's Pleas of the Crown, 429.

<sup>2</sup> Small v. Howard, 128 Mass. Reports, 131, and cases there cited.

<sup>3</sup> Musser's Executor v. Chase, 20 Ohio State Reports, 577.

the plaintiff contributed. If the third of these elements is wanting, that is to say, if the plaintiff has been guilty of any neglect or want of due care, to which the injury is in any material part attributable, he cannot maintain his action. The law will not hold one liable for an injury to another whose own default contributes to it, nor will it attempt to apportion the blame between them. Such an injury must lie where it falls. This principle of contributory negligence is constantly applied in actions of malpractice, with the result that the physician is not legally responsible for injuries attributable in any degree to the fault of the patient as an originating cause.<sup>1</sup> And the application of the principle to the case now supposed, of an action against an unskilled person for an injury done in a case which he has not professed himself competent to treat, seems to reinforce the argument against his liability, since it lays upon the plaintiff the disability which results from his own failure to exercise due care. If he calls an ordinary physician, relying, as he has a right to rely, upon his public profession of skill, and following his directions accordingly, no want of care can be imputed to him. But if he voluntarily chooses for the performance of a difficult and perilous task a person who neither has nor claims to have any special fitness for it, it is no hardship if he is left to bear the consequences of his own imprudence. In this conclusion the medical profession will probably concur with cheerful unanimity.

This latter branch of the subject still lies largely in the region of conjecture, and these suggestions are not offered with confidence as a statement of the law, but as having a possible bearing upon the determination of a question which has, fortunately, only an indirect interest for reputable physicians.

## REPORT OF A SUMMER COURSE IN OBSTETRICS.<sup>2</sup>

BY C. M. GREEN, M. D.]

In the summer of 1881 it was my fortune to instruct a class of six students in a course of clinical obstetrics. The material was kindly furnished me by the District Physicians of the Boston Dispensary, and was derived chiefly from the lowest class of the north and southeast parts of the city. The observations which I summarize below were made by the students; in most instances, however, they were verified by myself.

|            | Cases.          | Males. | Females. | Sex not Recorded. | Putrid Cases.  |
|------------|-----------------|--------|----------|-------------------|----------------|
| Multiparæ. | 27 <sup>2</sup> | 11     | 15       | 1                 | 1 male; 1 fem. |
| Primiparæ. | 8               | 5      | 3        |                   |                |
| Total . .  | 35              | 16     | 18       | 1                 | 2              |

Mortality : maternal *nil* ; infantile *nil*.

Abnormal symptoms during pregnancy : vomiting in early months four cases, one of which was obstinate ; vomiting in last months one case ; this was a case of twin pregnancy, and the gastric disturbance was prob-

<sup>1</sup> Hibbard v. Thompson, 109 Mass. Reports, 286.

<sup>2</sup> Read before the Boston Society for Medical Improvement, January 28, 1882.

<sup>3</sup> Including two cases of twin pregnancy.

ably due to the upward pressure of the greatly distended uterus.

Oedema of legs four cases, unattended by albuminuria.

Frequent micturition one case, relieved by a swathe.

Varix of labia one case, accompanied by severe cramps in the legs.

Ante-partem hæmorrhage one case ; about one ounce of blood escaped from the vagina on the sixth and again on the second day before delivery. The placenta was not prævia, but was very probably partly seated in the cervical zone, and the slight uterine contractions commonly occurring in the last weeks of pregnancy probably partially detached it.

### POSITION AND PRESENTATION.

| O. L. A. | O. R. A. | O. R. P. | S. L. A. | S. R. A. | Uncertain. | Total |
|----------|----------|----------|----------|----------|------------|-------|
| 23       | 6        | 4        | 1        | 1        | 2          | 37    |

It is worthy of notice that of the head presentations eighteen per cent. were O. R. A., or right occipitocotyloid, a larger proportion than is usually found in a large number of cases ; and that twelve per cent. were O. R. P., or right occipito-sacro-iliac, which is rather less than the usual ratio.

### AVERAGE DURATION OF THE STAGES OF LABOR.

|               | 1st Stage.              | 2d Stage.            | 3d Stage.         |
|---------------|-------------------------|----------------------|-------------------|
| Primiparæ . . | 11 h. 13 m. (22 cases.) | 56 m. (22 cases.)    | 19 m. (20 cases.) |
| Multiparæ . . | 24 h. 29 m. (8 cases.)  | 2 h. 7 m. (7 cases.) | 21 m. (6 cases.)  |

### CASES OF ESPECIAL INTEREST.

#### a. Cases of twins :—

(1.) A multipara, aged thirty-six, bore twins after a labor of ten hours. The children were male and female, and both presented the occiput. The second fœtus, which was smaller than the first, was born with membranes intact, or, as popularly designated, with a caul. There was a single large placenta, with a dividing ridge and two cords.

(2.) A multipara, aged twenty-seven, gave birth to two boys, the first presenting O. L. A., the second S. R. A. The diagnosis of twins was made by the student by abdominal palpation and auscultation. The placenta was double, and there were two cords.

#### b. Case of miscarriage, with dead fœtus :—

This case is of interest as affording a clear history of the cause of death of the fœtus. July 5th, when about six and one half months pregnant, while on Boston Common seeing the fireworks with her little boy, the latter being lost in the crowd, she spent two or three hours seeking for him, and returned home much fatigued. From this time she ceased to feel fetal motion, and experienced the sensation of having a cold, hard lump in the lower part of the abdomen. A month later she was delivered of a dead fœtus with macerated epidermis.

#### c. Case of brow presentation :—

This occurred in an Italian woman, aged thirty-five, whose two previous labors had lasted three and two days respectively, but which had terminated without operative interference. The woman had been in labor over thirty-six hours before the head passed the superior strait. On the occurrence of the first strong pain pressure

<sup>4</sup> In one case the head became extended and the brow presented.

upward was exerted on the frontal bones and the head flexed; the occiput then rotated forward, and the child was born without further difficulty. This is doubtless one of those cases in which, with a slightly narrowed pelvis, the head becomes extended in its efforts to pass the brim, and the bitemporal diameter passes where the somewhat larger sub-occipito-bregmatic diameter will not. Schroeder mentions this mechanism as affording good evidence of a slight pelvic flatness. Such malpresentations often correct themselves in the cavity of the pelvis, and thus escape notice unless detected early in the labor.

*d.* Cases of instrumental interference:—

(1.) A multipara, aged twenty-seven, whose last three of five children had been still-born, had been fifteen hours in labor when the pains proved ineffectual. The head was on the perineum, and the child was undoubtedly dead. At this juncture the student summoned a physician, who applied forceps and delivered the head, but was unable to deliver the body. One drachm of fluid extract of ergot was administered, and the putrid fetus was finally delivered by traction. The placenta was adherent, and it was necessary to introduce the hand into the uterus to remove it; it was small and shrunken. The woman was doubtless syphilitic. I mention this case in order to criticize (perhaps ungraciously) the application of forceps to a putrid head; the cranioclast would in my judgment have been more suitable and safer. I also disbelieve in giving ergot to stimulate a uterus to expel even a putrid child; for if the placenta is adherent, as it was in this case, it is much more difficult of removal when the uterus has firmly contracted upon it.

(2.) A primipara, aged twenty-four, had been in labor forty-eight hours, and the first stage was not completed; she had received forty-five grains of chloral hydrate in fifteen-grain doses; she had also had ether. As the pains were ineffectual the dilatation of the cervix was completed manually and forceps applied. To avoid rupture of the perineum it was incised laterally. The placenta was retained, and, failing to express it after the manner of Credé, I passed my hand into the uterus and found the placenta to be partially adherent and encysted; dilating the constriction with the hand, I removed the placenta without difficulty. The woman received carbolyzed douches for a week, and made a good recovery.

(3.) A primipara, aged twenty-four, had been in labor twenty-four hours, and the os was about half dilated. The head had not entered the pelvis, and as there was a good degree of hydramnios it was decided to rupture the membranes. The head now engaged in the brim but did not advance, owing to uterine inertia. At the end of another twenty-four hours, during which time the woman's condition remained good, forceps were applied at the superior strait. After strong traction a large child was safely delivered, but the perineum was completely ruptured, the tear extending 1.5 inches up the rectum. It was decided not to perform the primary operation on the perineum; the urine was drawn by catheter for a week, and during two weeks the woman received carbolyzed vaginal douches. At the end of this time it was found that the rectal tear had entirely healed; when she first got up the woman had one involuntary defecation, but since that time she has had complete control of sphincter. To prevent future displacements of the uterus, however, the operation for restoring the perineal body will

be performed at the completion of lactation. Examination with a Sims's speculum revealed a stellate laceration of the cervix, but not of sufficient extent to need treatment.

#### MANAGEMENT OF THE PERINEUM.

Students were instructed to prevent the passage of the head through the outlet until the perineum was completely dilated; to accomplish this they were to bid the woman cease bearing down, and to exert forcible counterpressure, if necessary, on the head. They were also taught to extrude the head between the pains by careful manipulation after the occiput had passed under the pubic arch. The results of their practice were as follows:—

Of eight primiparae, perineum not ruptured, four cases;<sup>1</sup> perineum slightly ruptured, two cases, needed no operation; perineum ruptured nearly to anus, one case, refused operation; perineum completely ruptured, one case.—high forceps case alluded to above, in which the rectum and sphincter healed spontaneously.

Of twenty-six multiparae perineum not ruptured in any case, possibly because sufficient rupture had occurred in previous labors.

#### TREATMENT OF THE THIRD STAGE.

In three of the thirty-five cases the placenta was retained, and it was necessary to pass the hand into the uterus to deliver it; in ten cases the placenta was expelled by the contracting uterus, either with the child or within twenty minutes; in the remaining cases the method of Credé was employed. One drachm of fluid extract of ergot was then given, and the fundus supported by the hand until the uterus was firmly contracted and remained so. The patient was not left until an hour after the birth of the placenta.

There was one case of post-partum hæmorrhage. The patient became pale and restless, and was bathed in cold sweat; the pulse was 100. Failing to arrest the hæmorrhage with ergot, stimulants, and ice in the vagina, the student resorted to the use of persulphate of iron applied on a swab.

#### THE PUERPERAL STATE.

Nearly all the cases convalesced rapidly. There was no instance of septicæmia, due undoubtedly to the assiduity of the students in charge, who prescribed, and in many instances administered, carbolyzed vaginal douches whenever the lochia became fetid. Thirty-two women suckled their infants, and one was prevented from doing so by depressed nipples.

One case is of interest as showing how much a puerperal woman will sometimes endure without apparent harm. A multipara, aged thirty-three, was in the Danvers Asylum four years ago. Again, in March, 1881, she was sent to the Taunton Asylum, but was discharged about July 1st against advice. On July 5th she was consigned to the Tombs for extreme violence while under the influence of liquor, but was discharged the next day. At all times she was irritable, jealous of her husband, and she beat her children unmercifully. She was taken in labor August 14th, six weeks after her discharge from the Taunton Asylum. On the evening after the labor (which was normal) she demanded some liquor of her husband. She then got up, and proceeded, among other things, to wash

<sup>1</sup> In one forceps case rupture was prevented only by making lateral incisions.

soiled linen by placing it on the floor and pouring water over it, to the discomfiture of the tenants below her; she also cooked and eat beefsteak. The baby was fed on watermelon and whiskey, and finally quieted with laudanum. The next morning, beyond looking somewhat wild and disarranged, the woman showed no ill effects; the pulse and temperature were normal. It seemed to me, considering the woman's history, that this could scarcely be regarded as an instance of intoxication simply, but rather an outburst of transitory mania, of which alcohol was the exciting cause.

### IS ACUTE FOLLICULAR TONSILLITIS A CONSTITUTIONAL DISEASE?<sup>1</sup>

BY DR. MORTON PRINCE.

ASIDE from the severity of the symptoms which sometimes accompany acute follicular tonsillitis or catarrhal sore throat, the frequency with which the disease occurs seems to me to endow it with an importance which is rarely granted it. In the opinion of the reader there is no similar self-limited disease which is capable of producing in so short a time such a profound impression upon the strength and well-being of the patient as acute follicular inflammation of the tonsils. So severe are the constitutional symptoms that are often met with, that I have been led to believe, contrary to the general opinion, that this affection, in a large number of cases, should not be regarded as a local disease, but rather be classed among the constitutional fevers; and this belief has been confirmed by what I believe to be a fact, and that is, that there is no constant relation between the local lesion and the general disturbances. It has been the experience of the reader that, along with a local inflammation of an apparently trifling nature, there may occur a very high fever, severe headache, backache, loss of flesh, and what perhaps is the most striking symptom, extreme prostration and weakness. So marked, indeed, is this last symptom that I have known patients, after a four or five days' attack, to present the appearance of a convalescent from a mild attack of typhoid. And the converse of this is also true, that along with very severe local inflammation the constitutional symptoms may be of only moderate severity. In confirmation of these statements I will mention, in brief, the following cases, selected simply because the histories are known in full.

Case I. Self; at the time house officer in the Boston City Hospital. Woke up one morning feeling poorly, and with a sore throat; towards noon felt feverish; while making the morning visit had a chill; went to bed with a temperature of 103° F. During the next three days the temperature varied between 103° and 104° F., and on the fifth day subsided. During most of this time there was very severe headache, but the most prominent symptom besides the fever was a backache, which was excruciating. For this last it was necessary to give morphia subcutaneously in one fourth grain doses. There was a tendency to delirium, as shown by its being present for a few minutes after waking. The throat was very sore, especially on swallowing. In the glass I could see that the tonsils were reddened, moderately enlarged, and from the mouths of the follicles exuded a white secretion. There was also some redness of the pharynx

and neighboring parts. There was great loss of strength and some loss of flesh. These persisted for some days after cessation of the acute symptoms. I never had an attack before or since.

Case II. Mr. A., clerk, age twenty-three, came home in the evening complaining of sore throat and fever. The fever lasted three days, the maximum point reached being 101° F. During this time was very somnolent, sleeping heavily most of the time. He complained mostly of severe headache and backache. There was complete anorexia notwithstanding the high fever. The local disturbance was slight, not being even sufficient to elicit particular complaint, or to induce him to use the gargle which was prescribed. On inspection the tonsils were seen to be slightly enlarged and reddened, as were also the neighboring parts. Two or three white spots marking the mouths of the occluded and inflamed follicles could be made out upon the tonsils. The subsidence of the fever was rapid, as in Case I., leaving the patient pale and in a debilitated condition, from which it took some time to recuperate. He never had a similar affection before or since.

Case III. Mr. B., merchant, age thirty-one, returned home one afternoon complaining of slight sore throat, headache, and general malaise. That night he had a chill; temperature was 102° F.; tonsils slightly enlarged and reddened, one or two white spots, as in the preceding case, marked the mouths of the inflamed follicles; there was no marked soreness of the throat; was able to swallow readily without great pain. The patient complained principally of headache. The next morning the thermometer recorded only 101° F.; during the day he complained principally of headache, backache, and general weakness; there was great drowsiness, the patient saying that he could not keep awake; no appetite; the same evening temperature rose to 102.5° F., the highest reached; the next day it fell to normal, and there was a subsidence of the symptoms, but the patient was left weak and prostrated, and convalescence required a number of days. Though this patient has what is called a "delicate throat," he never had such an attack before or since.

Case IV. Miss X., age twenty-seven, was ill for four days with follicular tonsillitis. The local symptoms were moderately severe; complained of considerable pain on swallowing; the tonsils were slightly enlarged, reddened, and from the mouths of several follicles exuded a white secretion, which could be pressed out and removed with a probe; the temperature ranged about 102° F.; there was great headache and backache, which persisted most of the time, and gave rise to considerable complaint; the strength of the patient was considerably reduced, and she was left in the same debilitated condition as in the other cases, with slow convalescence, lasting a week or more. Although it might be easy to multiply cases, I do not consider it necessary, as it would make dull reading, and one case is nearly a repetition of another.

There is one difficulty in collecting statistics from a large number of cases, and that is the physician is not usually called till after the disease has reached its maximum intensity, so that the first stage is not usually recorded, and any observation of the temperature is apt to be imperfect. Further, as the disease tends to spontaneous recovery without danger, the services of a physician can be quickly dispensed with.

In the cases just reported it will be noticed that in

<sup>1</sup> Read before the Suffolk District Medical Society, December 31, 1881.

Cases II. and III. the local disturbance was so slight as hardly to call for treatment, and yet the general symptoms were very severe. Again, in Case II., while the tonsils were only slightly inflamed the temperature was high, reaching  $104^{\circ}$  F., but in case III., with about the same amount of tonsillitis, the temperature was very moderate, but notwithstanding this moderate temperature and slight local inflammation, the constitutional disturbance was very considerable. This patient frequently remarked during convalescence, "How," to use his expression, "tonsillitis pulled one down." In Case I., on the other hand, both the local and general symptoms were very severe, and in Case IV. they were moderately so. In none of them did the inflammation extend to any marked extent to the parenchyma of the tonsils as in the other variety which so often leads to abscess. On the contrary, the tonsillitis was of a follicular or catarrhal character, and the neighboring structures were only so far implicated as to show reddening of the mucous membrane.

The question arises, Why should not the constitutional disturbances met with be considered as dependent simply upon the local inflammation? Of course it is impossible to absolutely disprove such a possibility, but it does not seem to me that a local inflammation alone can satisfactorily explain the symptoms. That the constitutional disturbances are not due to the high temperature is shown by the fact that in many cases, as in III. and IV., the fever may be of only slight intensity, and yet the other constitutional symptoms were very marked.

Four cases are too few to found a hypothesis upon, and I do not present them for that purpose, but rather as types of a large number of cases which it has been my good fortune to meet during the past year, and which were studied with particular reference to the point under discussion.

I think the following conclusions may be safely drawn:—

First. There is no constant relation between the local inflammation and the constitutional symptoms.

Second. There is no constant relation between the local inflammation and the height of the fever.

Third. There is no constant relation between the height of the fever and the remaining constitutional symptoms.

Fourth. The fever is often so high, sometimes reaching  $105^{\circ}$  F., as to be far out of proportion to the local inflammation, which may be slight.

Fifth. With slight fever and slight local inflammation we may have severe constitutional disturbances, such as weakness, loss of appetite, headache, backache, general prostration, and prolonged convalescence.

Another thing which is suggestive of the constitutional character of this affection is the frequency with which it occurs amongst internes and nurses in the hospitals. I have taken pains to obtain some statistics which would determine this point, and have been able to obtain accurate information in regard to twenty-seven of the past house officers of the Boston City Hospital, principally by letter, or by direct inquiry of each individual himself. Of these twenty-seven, I find that seventeen had "hospital sore throat" while serving in the hospital, and ten did not. Consequently *sixty-three per cent.* of the internes suffer from the disease during their service.<sup>1</sup> Several gentlemen have

kindly sent me accounts of their attacks. One writes that he had two attacks, one while externe. He says "It was a follicular inflammation of the tonsils, and confined to the right side; lasted ten days; it was very exhausting. Temperature rose to  $105^{\circ}$  F. the first night. In four days I was out, but did not return to duty until the tenth day. The second attack was when I was house surgeon, and during the second month of my service. . . . During the last month before I was taken ill we had a good many erysipelas cases, and three pyemias, one of which was the worst I ever expect to see. Dr. ——— was my junior at the time. After I recovered he was taken down, and gave up for over two weeks. This second attack was similar to the first, but much more prostrating, and laid me up for two weeks. . . . My cousin, Dr. ———, had two severe attacks while at the hospital, and he was much more prostrated than I."

Dr. Withington, of the Boston City Hospital, has, at my request, kindly made inquiries amongst the house officers and nurses at present in the hospital, and furnished me with the following account: Of ten house officers six, or sixty per cent., have had the disease, and four have not. All of these four are juniors with six months now of service before them, and consequently, I may remark, with plenty of time before them in which to catch the disease. Of thirty-two women, mostly nurses, nineteen, or fifty-nine per cent., have had the affection, and thirteen have not. This ratio may be increased by some of these thirteen taking the disease before leaving the training-school.

Since these inquiries were made, Dr. Withington has kindly informed me of an epidemic which occurred lately amongst the nurses connected with the uterine ward. In one week seven nurses employed in this ward were taken ill with follicular tonsillitis. None of the patients in the ward took the disease, and there were no cases of diphtheria or other contagious disease there. The water-closet, which was suspected, proved on examination to be in good order. There were no cases in other wards at this time.

This great frequency of tonsillitis in the hospitals, of course, does not of itself prove the constitutional nature of the disease, but taken in connection with other facts, such as the great severity of the symptoms often observed under these conditions, and the fact that the number of cases is sometimes sufficient to justify the term epidemic, it is enough, to say the least, to make one suspect that, whether local or general, it is caused by some of the many morbid influences by which one is surrounded in a hospital; and if this is so, it is more in accordance with our knowledge of the influence of such poisons on the organism that a general disease should result than a local one.

In regard to the origin of the so-called septic cause of tonsillitis I do not pretend to advance an opinion. The cases I have investigated in regard to this point are too few, but it may be proper to state that of the four cases recorded above one occurred in the hospital and three at different times in the same house, in which the drains were so extensively out of order that the odor of sewer gas was plainly perceptible. And in dispensary practice I have again and again met with cases where the hygienic surroundings were wretched, though I could not positively say the drains were defective, however much it might be suspected from the foul smells present.

Another point in favor of the septic nature and

<sup>1</sup> I think this percentage is slightly too high, as there is a source of fallacy in the possible error of diagnosis.

constitutional character of this form of tonsillitis is to be found in those cases which occasionally occur in an epidemic form. An epidemic of this kind has lately been reported<sup>1</sup> by Dr. George Wilson as occurring in the Rugby School, England.

In this epidemic the disease appeared in three out of the eight boarding houses, and about thirty boys in each house were more or less affected, making about ninety boys in all. Dr. Wilson thought he had traced the cause of the epidemic to infected milk; one of the cows belonging to the milkman who supplied the school being found to have garget. This seemed to be confirmed by the fact that, out of thirty-seven families in the town who were supplied with milk by this dealer, in fifteen, one or more members were more or less affected. Clement Dukes, physician to the school, in a letter to the *British Medical Journal*,<sup>2</sup> attempts to disprove the milk-infection theory, and thinks that the disease was due, like influenza, to atmospheric influences.

He thus describes the principal characteristics of the epidemic:—

- "(1.) Sudden onset of feeling of cold water being poured down the back, feverishness, aching of the limbs, headache, *malaise*.
- "(2.) Very painful stiff neck.
- "(3.) Enlargement of submaxillary glands.
- "(4.) Ordinary catarrhal sore throat in the majority of cases, but in some absent throughout.
- "(5.) It lasted about forty-eight hours.
- "(6.) Was in a few cases attended by sequelæ, true quinsy, pleurisy, acute rheumatism, and considerable debility.
- "(7.) None were followed by paralysis."

"The symptoms were analogous to — I may say identical with — influenza, with the exception that instead of catarrh of the eyes and nose we had catarrhal sore throat." He further declares that it was very infectious, that several went home and infected their friends, and that one person caught it in the railway train from two boys who had had the sore throat.

Dr. Ernest W. Cushing has kindly, at my request, furnished me with an account of an epidemic which he witnessed on board ship, and from which he himself was a sufferer.

"In September, 1869, the steamship *Holsatia* left New York for Hamburg with about thirty first cabin passengers and perhaps three hundred other persons, including the crew. One of the passengers in the first cabin was just recovering from an amygdalitis.

"On about the seventh day of the voyage several of the other cabin passengers were attacked by severe amygdalitis, with chilliness and fever lasting for some days, and dysphagia, great weakness, and prostration. Within a few days more than half of the cabin passengers were attacked with the same malady, which lasted about a week in the milder cases, longer in the more severe ones. One passenger landed at Plymouth, feeling too ill to proceed further. One elderly lady who landed at Cherbourg had to stay there a fortnight before she was able to travel.

"Two of the passengers entered the hospital at Hamburg, very ill.

"The surgeon of the ship used various gargles, etc., none of which apparently were of much use; one of permanganate of potash appeared to be injurious. The best was simply milk in which a fig had been boiled. There was no difficulty in respiration in any case, nor any patches on the soft palate, nor any induration of the submaxillary glands. The tonsils were swollen and inflamed, but did not suppurate; there were follicular ulcerations and white deposits in some cases, much resembling

diphtheria on casual observation. The soft palate and uvula were swollen, and the pharynx was covered with a tenacious mucus, causing incessant and atrociously painful efforts at swallowing. There were no cases among the crew nor among the steerage or second cabin passengers.

"This appeared to be a clear case of epidemic follicular amygdalitis, with a period of incubation and a distinct source of contagion, a constitutional affection, commencing with repeated light chills and decided fever; a period of great prostration lasting long after the violence of the local inflammation was over.

"The writer, who was himself a sufferer, has a very clear recollection of the facts, and remembers that Dr. Alonzo Clark, in his lectures, mentioned the occurrence of such epidemics. The last cases were more severe than the first. The sanitary condition of the ship was perfect, water and food excellent, weather fine during the whole voyage."

One epidemic, studied and reported by Flint, has thus been summarized by him:—

"The disease was an epidemic fever characterized by mild erythematic inflammation of the fauces as a constant local complication. Its character as essentially a fever is established by the febrile movement being in a marked degree out of proportion to the local affection. In other words, evidently not being symptomatic of the latter, and by its running a definite although a brief career. It was a fever of from three to five days' duration. Its epidemic character is sufficiently apparent. It prevailed extensively for about two months, reaching its acme gradually, declining gradually, and at length disappearing, affecting both sexes and different ages without discrimination.

"The small white patches . . . were evidently due to follicular secretion."

Now if we compare those cases occurring during an epidemic with the sporadic cases we shall find very little if any difference between them. The symptoms in both are essentially the same. The onset of an attack, the fever, the local lesion, the constitutional disturbance, the course and duration, are similar, and if the one is regarded as a constitutional fever I do not see why the other should not be also. I see no more reason for regarding epidemic tonsillitis as a so-called essential fever, and sporadic tonsillitis as a local affection, than for considering scarlatina to be a constitutional disease when it occurs in epidemic form and an erythema of the skin when it happens to be sporadic.

Furthermore, as the distinction between sporadic and epidemic cases is merely an arbitrary one, depending upon the number of cases occurring during any one period, any such distinction cannot have reference to the nature of the disease but only to the origin. The term epidemic hangs upon a sliding scale and may be pushed backward or forward at will.

In regard to the disease being infectious the following facts are suggestive merely. A patient of Dr. A. L. Mason was ill with what he (Dr. M.) tells me was acute follicular tonsillitis. Towards convalescence this patient was seen by one of mine reported above as No. III. Two or three days later No. III. was taken ill with the disease. Furthermore, three servants in the house with Dr. Mason's patient were successively attacked with sore throat at intervals of two or three days of each other. Unfortunately they were not seen by a physician, but, on the principle of what is good for the mistress is good for the maid, were treated with Dr. Mason's prescription. They were probably light cases. Four persons were accordingly attacked with sore throat after coming in contact with a person having follicular tonsillitis. I have repeatedly seen two or three persons in the same family successively attacked.

One argument which is constantly employed against the usefulness of the many remedies which are every day offered and highly extolled for the cure of diph-

<sup>1</sup> Abstract of Dr. Wilson's report in the *British Medical Journal*, September 3, 1881.

<sup>2</sup> September 24, 1881.

theria, is that many physicians meet with a large number of cases of diphtheria in their practice with a high percentage of recoveries, while another class of physicians see but little diphtheria and many cases of tonsillitis. It is generally held, and I must believe with truth, that a large proportion of the cases of diphtheria of the former class of physicians are merely cases of tonsillitis which have recovered from the natural self-limitation of the disease. And I think it is probable that the observers have been misled by the constitutional character of the symptoms so strikingly manifested. It is also much more difficult than is generally allowed to distinguish by mere inspection diphtheritic patches on the tonsils from the exudation due to follicular tonsillitis. Both often have to the eye the same appearance. And I have been able on several occasions by means of a reflector and a probe to prove what has been thought to be the exudation of tonsillitis to be in reality diphtheritic, and *vice versa*. Gargling is very inadequate as a test. In cases of doubt the probe should always be used.

On referring to the text-books I have been both surprised and disappointed. I find much, though, to support this view of the disease, although no writer, so far as I am aware, pronounces positively in its favor. Thus Mackenzie, without referring to any particular form of tonsillitis, says:—

"In those of debilitated constitution the fever occasionally assumes a typhoid character, whilst the local affection after a few days subsides into a subacute form in which the tonsils are partly covered with an ash-y exudation or honey-combed with ragged and indolent ulcerations."

Again:—

"Tonsillitis seems to have occurred in an epidemic form in some few instances, but from the published accounts there is great difficulty in distinguishing cases of simple tonsillitis from epidemics of scarlet fever. One instance, however, has been described with such care and precision by Mayence that little doubt can remain as to the purely tonsillar nature of the malady."

Cohen is very unsatisfactory, not distinguishing between the follicular and parenchymatous varieties.

Mandl dismisses the whole subject with a few words.

Bosworth, on the other hand, remarks:—

"The cause of this affection is from taking cold in a majority of cases; and yet behind this there is probably some especially predisposing cause of which we are ignorant. That it is something in the nature of an essential fever there is good ground for supposing; yet that it is contagious I do not believe. It often prevails somewhat as an epidemic and also endemically."

Among the works on general medicine those of Aitken, Jaccoud, Todd, and Bartholow do not mention the subject. Trousseau lays great stress upon the constitutional symptoms, but does not distinguish between the parenchymatous and follicular varieties, and regards it as a local affection. Squaney,<sup>1</sup> under common inflammation of the fauces, describes an affection similar to the one under discussion. He looks upon it as a local affection, due to damp and cold. He nevertheless says, "Overwork, especially when combined with the effects of a vitiated atmosphere, as is so often found in hospitals, gives rise so constantly on the least chill to this affection that the name 'hospital sore throat' is very commonly applied to it." Wagner,<sup>2</sup> Desnos,<sup>3</sup> and Niemeyer take the same view in regard to its local character. Flint regards the affection as constitutional in character when occurring in epidemic form; the sporadic

cases he seems to regard as a local inflammation merely, due to catching cold. Roberts, in enumerating the causes of acute inflammatory affections of the throat, says:—

"Certain forms of throat inflammation may perhaps be due to some poison in the atmosphere acting on the system. Some cases of hospital sore throat seem to arise in this way."

The following conclusions may now be added to what has been previously said:—

Sixth. The disease occurs in an epidemic form, when it is undoubtedly constitutional.

Seventh. There are strong, though not conclusive, reasons for believing it to be more or less infectious.

Eighth. The frequency with which it occurs in hospitals is such as to be best explained on the theory of a septic action on the system.

Ninth. It is probably often mistaken for diphtheria, from which it differs greatly in its symptoms and course.

Though I have endeavored in the above remarks to bring forward evidence in favor of the constitutional nature of acute follicular tonsillitis or catarrhal sore throat, I do not wish to be understood to maintain that every case of tonsillitis in which the follicles are involved is in reality a constitutional fever. On the contrary, cases of catarrhal inflammation of the throat, of a very simple nature and involving the tonsils, undoubtedly occur with considerable frequency. Such is to be expected, and there is no good reason why we should not have a simple inflammation of the tonsils dependent on cold or other influences as of the mucous membrane in other regions. But what I wish to draw attention to is this: that there is good reason to believe that *there is a form of sore throat of common occurrence in which the follicles and mucous membrane of the tonsils are chiefly involved, and which is the localized expression of an essential fever, not generally recognized.*

## RECENT PROGRESS IN FORENSIC MEDICINE.

BY F. W. DRAPER, M. D.

### DEATH BY DROWNING.

For a long time, authors have been particular to describe the special characters which are presented by the blood of those who have died by drowning. They have noted its color, its great fluidity, and the general absence of clots in the heart's cavities and in the great vessels. But hitherto no one has sufficiently indicated the cause of these changes and the conditions which determine their slight manifestation in some instances, their total absence in others. Recently this subject has been reviewed by MM. Brouardel and Vibert,<sup>4</sup> and their conclusions form an interesting chapter upon this important medico-legal topic.

The authors ask at the outset, "Does water reach the blood in appreciable amount during the act of drowning; and, secondly, if it does so, by what channel does it enter?" To ascertain if water really penetrates to the blood of the drowned, and to measure its amount, the experiment was tried of counting the number of blood-globules in a given volume of blood of an animal before and after submersion; and it was found that the number of globules was diminished by one quarter, and in some cases by one third, if the death

<sup>1</sup> Reynolds's System of Medicine.

<sup>2</sup> Ziemssen's Cyclopadia of Medicine.

<sup>3</sup> Nouv. Dict. de Méd.

<sup>4</sup> Etude sur la Submersion. Ann. d'Hygiène publique et de Méd. légale. Third ser., IV., 1880, page 452.

was induced slowly, the diminution being appreciably in proportion to the duration of the submersion: That this change was due to an actual increase in the aqueous part of the plasma, and not to a disappearance of the globules by the destructive agency of the water, the authors satisfied themselves experimentally.

If the animals experimented on were drowned rapidly, that is, by holding the head constantly under water till death was assured, the blood-globules presented no change in their relative number.

The channel by which the water reaches the blood is chiefly the pulmonary mucous membrane; the gastric mucous membrane, while aiding in the process, is of secondary importance, its power to absorb the water introduced into its cavity being relatively feeble.

The authors believe that the introduction of this considerable volume of water into the blood in the act of drowning, while effecting certain gross anatomical changes in the blood as observed post mortem, is of very little consequence in the mechanism of the death, and determines on its own account no important phenomenon. Moreover, it is far from exercising on the blood-globules themselves any such effect as might be expected. In dogs whose blood was diluted one quarter or more, not more than five globules in every hundred were changed, the change consisting in the assumption of a more or less spherical shape with an increase in size and a loss of hæmoglobine.

Upon careful examination of the pulmonary parenchyma and alveoli of animals which had been drowned, the authors found numerous small capillary hæmorrhages, and it is from these hæmorrhages, and not from any escape of blood through the bronchial mucous membrane, that, according to these observers, the froth which appears at the nostrils and lips of the drowned gets its rosy tint. These minute capillary hæmorrhages are relatively rare; more often one finds upon the surface of the lungs quite large patches, well-defined in outline and of a rather deep color. These are true subpleural ecchymoses, remarkable for their extent, their thinness, and their situation. They consist of a uniform layer of blood-globules, not thicker than the pleura, which has itself been separated from the lung tissue by the extravasation.

Among other changes described by the authors as resulting from submersion is a granulo-fatty degeneration of many of the cells of the pulmonary epithelium which have been acted upon by the water absorbed in the course of the drowning. This degeneration may supervene with great rapidity; it has been observed within half an hour from the submersion.

The medico-legal applications, which the authors make of their experimental observations, are as follows:—

The first and most important point is this. When a man in drowning can come several times to the surface to breathe, when he drowns slowly, he absorbs by the lungs a considerable amount of water: he admits water to his blood to the amount of from one quarter to one third of the total volume of the blood. There results a decided fluidity of the blood and no clots are formed either in the heart or the great vessels. Moreover the blood thus changed transudes through the vessels with extreme readiness and when gaseous putrefaction of the intestines develops and forces the blood from the deeper parts toward the extremities and surface, this blood rapidly colors the cellular tissue which surrounds the vessels and renders difficult, if

not impossible, the diagnosis of contusions or sanguineous extravasations which had accompanied death or preceded it.

If the body bears one or several wounds the fluid blood escapes with great ease, and one might readily believe that the drowned victim has just been thrown into the water, and that his wounds are recent and still bleeding, when, as a matter of fact, the wounding may have occurred hours or even days before.

When, on the other hand, death has taken place rapidly, and the drowning man, for any reason whatever (syncope, cerebral concussion, intoxication), has sunk at once to the bottom of the water without coming to the surface to breathe, the quantity of water absorbed by the pulmonary surface is slight and insignificant. The lesions do not differ materially from those which one finds after death by suffocation in a sand-bank or in grain, or in any irrespirable, but not poisonous, medium. The heart may then contain clots.

One understands, too, how in death by drowning which has been rapid there may be clearly defined, punctate, subpleural ecchymoses; in slow death, under water, on the contrary, these punctate ecchymoses are replaced by sanguineous extravasations which are large, expanded, and less striking. The difference in the two cases depends on the difference in the constitution of the blood.

The presence of blood-globules in the froth that issues from the bronchi of the drowned, especially in that found in the smaller bronchi, proves that the fine lather-like froth which we observe at the mouth and nostrils of a dead body recently taken from the water after drowning has its origin in the pulmonary alveoli, and is no proof that the drowning person came to the surface to breathe.

All these signs, taken together, will permit us to determine the conditions under which a drowned person has perished. If the blood is not fluid, if there are clots in the heart and punctate ecchymoses under the pleura, if the lungs do not present the peculiar appearance above described, which the authors call aqueous emphysema, we can say that the submersion occurred under circumstances that prevented the victim from struggling under impending asphyxia. If, on the other hand, the lungs are filled with water, if the blood is fluid, if the subpleural ecchymoses are large and somewhat indistinct, if the heart does not contain clots, we may conclude that the submersion has been slow and that the death has supervened upon a struggle, more or less instinctive in character, which has permitted successive mouthfuls of water to enter the trachea and to be absorbed by the pulmonary mucous membrane.

#### MEDICAL EXPERT TESTIMONY.

This is a topic of considerable concern to all who take any interest in forensic medicine. It will engage attention and excite discussion so long as the present deplorable methods of using medical opinion in court remain unchanged, and until the reasonable demands of the profession are heeded and some improvement is made in the traditional manner of exhibiting medical men on the witness-stand. All physicians, with the possible exception of a few who make the position of medical expert a matter of trade speculation, agree concerning the evils of the prevailing usage; but there is an unfortunate disagreement with regard to remedial treatment. Every year witnesses the publication of some new plan designed to meet the case. For ex-

ample, we find in a recent article<sup>1</sup> a very suggestive discussion of the whole subject by Prof. John J. Reese, whose experience and knowledge in all medico-legal matters endow his opinions with the title of authority. Dr. Reese recognizes to their fullest extent the defects already alluded to, points out the mischief resulting from the readiness with which many ignorant men, who call themselves "experts," are admitted to the witness-stand, describes the facility with which physicians of pronounced views lend their aid to partisanship, and denounces the still graver fault of our American method whereby "experts" make their views the subject of barter to the parties employing them and their fees conditional on the influence of their testimony.

The only true method, according to Dr. Reese, of meeting the difficulty, is to adopt a modification of the Prussian system. Let there be appointed, he says, for each of our States one or more thoroughly-educated practical physicians, properly trained in all the details of medical jurisprudence, including toxicology. These shall be known as State Medical Experts. The duties of such an official shall be to attend at every criminal trial in his district, when summoned by the court, as the skilled witness of the prosecution. He shall sit with the judges throughout the trial as *amicus curiæ*. He shall be prepared to make all requisite medical, microscopical, and toxicological investigations in any case requiring them. He should possess a chemical laboratory and all other appliances necessary to the thorough fulfillment of his duties. Although summoned by the State, he is by no means to be regarded in the light of a partisan, any more than the judge upon the bench. He can have no temptation to bias for either side. He would render his "opinion" grounded solely upon truth; and both his moral and professional character and attainments should be such as to preclude the possibility of error so far as human infirmity may admit.

In most criminal trials, the testimony of such an official expert would be deemed fully adequate to settle all scientific questions by both sides; but the defense should have the right of employing their own expert witnesses. The salary of the State expert should be sufficient to command the very best talent, inasmuch as he would necessarily be compelled to relinquish all practice and devote his time exclusively to his arduous public duties. He should not be appointed by the legislature, for the office should be lifted high above all political favoritism; nor by the Governor of the State, for similar reasons; nor by the State Medical Society because of the risk of ring influence; but by the judges of the Supreme Court of the State as being the safest body with whom to lodge the responsibility.

Whether it be practicable or not, Dr. Reese's plan has the merit of being positive and specific. It is in sharp contrast with the conclusions offered by a committee of the Connecticut Medical Society at the last annual meeting of that body.<sup>2</sup> The committee, which included in its number the president elect of the Society, having labored with the problem a whole year, "regret to find that they can suggest nothing of such positive or practical value as they and perhaps others anticipated." They admit the imperative need for some amendment, and do not hesitate to denounce the evils of the prevailing system. They say we must

bear these evils because we must not lightly infringe upon "the natural, fundamental, common-law, and common-sense right of an accused person to bring his own witnesses into court, to confront and freely question all witnesses, and, however many experts may have testified, to bring his own, as many as he is able or thinks proper. This right accords with the English notion of fair play, and never will be conceded or essentially modified." It is admitted that great mischief comes out of this, "but we see as the basis and foundation of our system the rights of the common man, and forgive the special evil through love of the principle."

After discussing the subject in its various bearings, the committee suggests that "the only remedy for a better condition of medical expert testimony lies with the profession itself. In elevating its general tone, encouraging learning and devotion to study, a high personal sense of honor and of the worth and dignity of the body, with a determination to do nothing unworthily, making the expert an honest, learned, reliable, common-sense man,—this seems about the extent of our remedial measures." [Prognosis very doubtful! REP.] The conclusion of the whole matter, according to the Connecticut view, is that "when the expert is content to speak only the honest truth, and the lawyer to seek only for the honest truth, then there will come about a better and more pleasant feeling than now prevails!"

[Better, as it seems to the writer, than either the radical and heroic line of treatment which Dr. Reese elucidates, whose final product would be an omniscient and infallible doctor coordinate with the chief justice, or the truly expectant course prescribed by the Connecticut consultants, whereby the desired amelioration might be realized when all litigation and criminal prosecutions had disappeared from human experience by virtue of the prevalence of the "honest" truth, is the proposition advocated before the Massachusetts Medico-Legal Society, and embodied in the following sections of a bill drawn for legislative action:—

Section 1. In any action, suit, or proceeding, civil or criminal, in which the testimony of a medical expert witness is desired by the parties, they may at any time before the trial file in the clerk's office a written agreement that such witness shall be summoned, designating him by name if agreed upon. The clerk shall thereupon issue a subpoena to the person designated, to be served in the manner provided by law. As soon as may be after service thereof the witness shall make such examination of the case as may in his judgment be necessary and practicable, and he shall attend as commanded in the subpoena, and answer such questions as may be put in relation to the case. . . .

Section 2. In any criminal proceeding the defendant may call and examine other medical expert witnesses in addition to those hereinbefore provided for, but at his own cost; and in such case other medical expert witnesses may be called and examined in behalf of the Commonwealth.]

IS "CONGESTION OF THE BRAIN" A CORRECT PATHOLOGICAL EXPRESSION?

In the course of his Croonian lectures on the influence of the circulation on the nervous system, delivered last spring before the Royal College of Physicians of London, Dr. Walter Moxon answers the question very emphatically in the negative.<sup>3</sup> After a very in-

<sup>1</sup> Philadelphia Medical Times, 1881, vol. xii, page 452.

<sup>2</sup> Proceedings of Connecticut Medical Society, 1881, page 24.

<sup>3</sup> Lancet, 1881, vol. i., Nos. 13 to 18.

structive analysis of the various anatomical, physical, and physiological elements involved in the subject. Dr. Moxon continues as follows:—

"Can you in any individual case prove by post-mortem appearances that death was caused by congestion of the brain, or even that a state of congestion of the brain or over-fullness of its blood-vessels preceded death? I believe these questions must be answered firmly in the negative. In establishing such a negative, one has to meet with a very strong prejudice, rooted in most tenacious grounds,—the grounds of convenience and of ancient and universal acceptance. After examining a body dead from brain symptoms, when all you are able to see in your examination is only that the veins are very full of blood, it is very convenient to be able to say that death was caused by congestion of the brain, and it sounds much better for a skilled witness than to say that death was caused by insensibility: so that the doctrine of congestion of the brain is convenient, and the universality of its acceptance may be illustrated by the naïve earnestness with which authors of great works adopt it. . . . We find writers giving four conditions as showing congestion. The first is the swollen state of the brain, so that it seems after removal from the calvaria almost too large for the cavity which contained it. The dura mater seems tightly stretched over it, and, on reflecting this, the convolutions appear broad and flattened, and the sulci less obvious. No allusion is made here to hypertrophy of the brain, which is known only, so authors say, by its causing a general enlargement of the whole organ. I have never seen such hypertrophy, but the flattening described has very frequently come under my observation, but always in the presence of some obvious cause of expansion of the brain, in the form, usually, of an increase of the intra-ventricular fluid or else of apoplectic bleeding or of tumor, in which case the swelling and flattening are more localized.

"The next evidence [of congestion of the brain] mentioned by writers is the distention of the veins and capillaries with blood, the veins are tortuous and varicose, the gray matter dark. Both this and the white matter show abundance of bloody points and gorged vessels, and the description ends with, 'It is extremely difficult to draw the line and say what is morbid and what is consistent with health.' Now, it is better, nay, it is necessary, to say firmly that it is simply impossible to draw the line and to say what is consistent with health. But the question is not about the degree of health to be inferred from a post mortem, but whether the mode of dying, the position of the body after death, or the manner of making the inspection will not determine the appearance of extreme over-fullness of the vessels of the brain of the dead person, independently of the conditions which were antecedent to all this. Can we infer from the amount of blood in the brain after death the amount during life? Kussmaul and Tenner, after numerous experiments, under various conditions and circumstances accurately predetermined, declare as the result of their investigations that they could not deduce any results from post-mortem examinations undertaken to ascertain the state of fullness before death of the most important parts of the vascular system. Now, if this is the conclusion where the conditions before and after death were determined and known, how can it be said that the amount of blood found after death in the human brain will show the amount present before

death when the conditions before and after death were unknown and undetermined?"

The author applies the same line of reasoning to other organs,—to the liver and to the stomach, with special reference to the appearances caused by sudden death by heart disease. He then continues: "During life, redness, when associated with swelling, heat, and pain, are at one with these associates in proving the existence of inflammation; but after death the redness, which was due to the enlarged scope of vascular play, ceases, because vascular play has ceased with life. The consequence is not doubtful, and it is quite certain that after death the redness goes from inflamed and congested parts. Such serious issues may turn upon this point that I think it very necessary to clearly recognize that no degree of redness, or pinkness, or over-fullness of blood about the brain or its membranes can prove that there was any morbid state of the circulation within the head before the act of dying. Death by asphyxia increases the amount of blood in the head, but a dependent position of the head after death, if only for a short time, will cause a similar increase. It should be taught that it is a sign of ignorance to say in a coroner's court that congestion of the brain was found on post-mortem examination to be the cause of the person's death."

[These emphatic words have an obvious medico-legal application. To those who are in the habit of making autopsies with what is deemed proper thoroughness for judicial purposes, and who have invariably opened the head of the cadaver with that end in view, and have noted and described, with more or less faithful attention to details, the blood supply of the brain and its meninges as an essential part of the examination, these new teachings will suggest the propriety of revising the usual interpretation of injected blood-vessels. But the observations of Moxon cannot serve to justify the examiner in omitting to examine the contents of the cranium in every instance of post-mortem inquiry in death by violence, no matter how evident the cause of death may seem to have been declared upon inspection of other regions of the body. If the medical jurist desires an excuse for saving himself extra labor with the saw, mallet, and knife when he thinks he has found the cause of death in some region below the head, he will find a distinguished American precedent in the record of the autopsy of late President Garfield; it will be remembered that before proceeding to the inspection of the body in that case it was "unanimously agreed not to open the head."]

#### THE CHARACTERISTIC APPEARANCE OF WOUNDS OF THE INTESTINES MADE DURING LIFE.

Accurate knowledge of the distinguishing marks by which to determine that a solution of continuity in an intestine is the result of violence to the living body rather than of accident during the autopsy is of very great importance to the medico-legal inspector; and Dr. W. F. Whitney has done good service in pointing out with clearness the means of differentiation.<sup>1</sup> The relation, he says, which the mucous coat bears to the edges of the wound is characteristic, and when carefully considered will leave little doubt as to the time when the wound was inflicted. In ante-mortem wounds the edges are covered by a protrusion of this mucous coat. The mucous membrane is loosely connected to the muscular coats and is movable upon them to a

<sup>1</sup> JOURNAL, 1881, cv., No. 3, page 54.

certain extent. If all the coats of the intestine are divided, the edges of the wound will gape from the retraction of the cut muscles, and the lax mucous coat is forced through the opening by the peristaltic movement as far as its attachments will permit and curls back over the edges of the wound through the action of its elastic fibres. Once over the edges of the wound, the membrane is not retracted again and in a few hours it develops inflammatory adhesions in its new position. Besides the new position and relations of the mucous coat, there is a slight thickening of all the coats immediately in the neighborhood of the wound from an infiltration with serum and new cells.

In a rupture or perforation from ulcer, the protrusion of the mucous membrane would not occur, because in these cases the mucous coat is extensively destroyed and fastened to the muscular coats by inflammation before the outer layers of tissue yield.

#### THE DIAGNOSIS OF BLOOD-STAINS BY THE MICROMETRIC METHOD.

Dr. J. G. Richardson, whose enthusiasm upon the subject is well-known, gives the following as a summary of his observations on the micrometry of red blood-corpuscles and their bearing on the diagnosis of blood-stains.<sup>1</sup>

(1.) That in unaltered blood-stains, as ordinarily produced by the sprinkling of drops of blood upon clothing, leather, wood, metal, etc., we can, by tinting with aniline or iodine, distinguish human blood-corpuscles from those of the ox, horse, sheep, and goat wherever the question is narrowed down by the circumstances of the case to these limits.

(2.) By the method of the author we can measure the size of the corpuscles and apply the two corroborative tests of tincture of guaiacum with ozonized ether and of spectrum analysis, to a single particle of blood-clot weighing less than one fifteen-thousandth part of a grain, a quantity barely visible to the naked eye.

(3.) Hence when an ignorant criminal attempts to explain suspicious blood-spots upon his clothing, weapons, etc., by attributing them to the ox, pig, sheep, or goat, or to any of the birds used for food, we can under favorable circumstances *absolutely disprove* his false statement and materially aid the cause of justice by breaking down his lying defense, even if twenty years have elapsed.

(4.) But if the accused person ascribes the tell-tale blood to a dog, an elephant, a capibara, or any other animal in Dr. Woodward's list, it is useless to attempt to dispute his story on microscopical evidence as to the size of the blood-corpuscles.

(5.) In cases of innocent persons wrongfully accused of murder and really stained with the blood of an ox, pig, or sheep, testimony of experts founded upon the measurement of the corpuscles would be valuable, but less conclusive, because under certain circumstances human blood-corpuscles may *shrink* to the size of those of the ox, while under no known conditions do ox or pig corpuscles *expand* to the magnitude of those in human blood.

(6.) In order to do away with ingenious objections of lawyers that the murdered person may have been affected with some disease which altered the size of his blood-disks, or that the articles of clothing, etc.,

upon which the stains were deposited had produced chemically or otherwise some similar change in their magnitude, it is very important promptly to obtain stains from the fresh blood of the victim made in the presence of witnesses upon portions of the prisoner's clothing or upon weapons analogous to those upon which suspicious red spots are found when he is arrested. When this cannot be done, spots of the murdered person's blood sprinkled on white paper, and fragments of his lungs and kidneys should be carefully preserved, the former by rapid drying, the latter by preservation in diluted alcohol. These precautions may, in any instance, prove to be of infinite importance.

## Hospital Practice and Clinical Memoranda.

### A CASE OF HEMOGLOBINURIA.

BY F. GORDON MOERILL, M. D.

A. B., aged thirty-nine, consulted me October 19, 1881. His previous history is as follows:—

He enjoyed good health until 1877, when he went to California, and assumed charge of a placer mine in a malarious district. During the next four years his life was one of exposure, and attended with great mental strain and anxiety. He soon contracted malaria, and more than once was obliged to leave his business and seek medical advice in San Francisco. Two years ago he had an enlargement of the spleen, which disappeared under treatment. From time to time he took large quantities of quinine. A few weeks previous to my first seeing him he came to Boston, and soon after arriving here began to present the symptoms which led him to consult me. His general aspect was thin, sallow, and very anæmic, and he complained of chills at irregular intervals, with headache, nausea, and general malaise. His pulse was 110, temperature 101° F. No enlargement of the spleen was detected. Two grains of sulphate of quinine four times a day were prescribed, with the result of stopping the chills, and obtaining some improvement in the general symptoms. November 3d he stated that he had passed (for the first time in his life, so far as he knew) "bloody urine." This had occurred several times on the previous day, but at night the urine was perfectly clear again. Tincture ferri chlorid., in twenty-drop doses, was ordered in addition to the quinine, and he promised to bring me a specimen of his urine should he notice any discoloration. November 12th he brought me a phial containing six ounces of urine of a dark-red color. He stated that he had had another attack during the interval succeeding his previous visit, but being very much occupied had kept about town all day, and found upon his return to his home in the afternoon that the redness of the urine had entirely disappeared. The specimen was found to be albuminous, specific gravity 1025. Reaction faintly acid. A dark-brown deposit showed amorphous granular matter, but no blood corpuscles or crystals of calcic oxalate under the microscope; occasional granular casts were seen. Each attack had been preceded by a slight rigor and considerable pain in the back; on one occasion the feet were wet and cold. The same treatment was continued, and when last seen (December 15th) the patient was apparently quite well. His color and general appearance

<sup>1</sup> Medical News and Abstract, April, 1881, page 214, from the American Medical Bi-Weekly.

were good, and he had had no further symptoms of urinary trouble.

The rarity of this affection would seem to warrant a brief review of facts resulting from observations of similar cases.

Of the various names suggested as appropriate to this disease, — hæmaturia, intermittent, periodic, paroxysmal hæmoglobinuria, and hæmoglobinuria a figure, the last would seem the best, as will be seen when I refer to the pathology. First observed in 1864, it has excited considerable attention abroad, more particularly in France and England, during the past two years. The symptoms preceding and during an attack are usually more marked than in the case I have reported. Never fatal in itself, occurring almost always in males (one case only in thirty was that of a female), the attack is preceded by a distinct rigor, and is accompanied with nausea, pain in the back and legs, and a sense of weakness. Occasionally retraction of the testicle has been observed. In a space of time varying from a few minutes to two hours the urine begins to present the characteristic appearance I have described. This may last a few hours, very rarely more than seven or eight. The intervals between the attacks vary from one or more days to a year, so that one is never justified in pronouncing a patient well unless he has been under observation a long time, say several winters. The urine, in addition to the appearances I have described, usually shows crystals of calcic oxalate. The color may vary from being slightly tinged to the deepest red. The amount of albumen present in any given specimen is said to be proportionate to the depth of color.

The etiology of the trouble remains obscure, but certain facts have been so frequently observed as to warrant one in accepting them as fixed. Exposure to cold will excite an attack in a person who is already subject to the disease. Warmth (however obtained) immediately after the premonitory symptoms will prevent the discoloration of the urine, which is then found to be albuminous only. Hence attacks at night, when people are usually comfortably housed, are very rare. I have been able to find but one case reported. It is now admitted that the discoloration of the urine is due to the presence of hæmoglobin. This fact has been repeatedly demonstrated by the use of the spectroscope. The theory that the presence of this element can be accounted for by some peculiar condition of the urine which destroys the red globules, and sets free the coloring matter (thus changing what would otherwise be a hæmaturia into a hæmoglobinuria), is easily disposed of by the fact that blood disks placed in urine already containing hæmoglobin only, preserve their form as seen under the microscope. The idea that a sudden congestion of the kidneys from exposure to cold in some way destroys the corpuscles, and at the same time squeezes out the coloring matter in the tubuli uriniferi would seem disproved by the fact that the disease can be artificially produced by the inhalation of certain gases, and also (in people already subjects of the disease) by the application of cold to a very limited surface. When and how the change in the blood takes place is not known, but the evidence is not in favor of the kidneys. The peculiarly sallow hue of the patient is thought by many to be due to the circulation of free hæmoglobin. Exactly what condition of the system renders a person liable to the trouble remains uncertain, but that in some cases syphilis plays

an important part seems established by the fact that two cases have been cured by Murri by specific treatment. These two remained under observation several winters, and continued well. Murri states that there is only one other case of recovery recorded, and here in addition to quinine mercury was used. At the necropsy of a man who was subject to the disease, a syphilitic lesion of the liver was discovered. A connection between hæmoglobinuria and malaria is hinted at by nearly all writers, and there certainly seems ground for this assumption in the case I have reported, although the patient may have had syphilis and concealed the fact. Hence, so far as treatment is concerned, we may place mercury, quinine, and iron in the front rank of drugs likely to be of benefit. Astringent remedies in ordinary use for hæmaturia and pilocarpine given to relieve a supposed renal congestion have been found useless.

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

JANUARY 23, 1882. DR. J. C. WARREN presided. DR. C. M. GREEN read a paper entitled

#### REPORT OF A SUMMER COURSE IN OBSTETRICS.

Vide page 99 of this journal.

DR. MINOT said that the more frequent employment of forceps of late years was not only a great saving of suffering to the mother, but rendered her convalescence more free from danger, and more rapid. He was accustomed to use forceps more frequently perhaps than most practitioners. In a series of 282 consecutive recorded cases in private practice he delivered the patients with forceps 92 times, or 32 per cent. of the whole number, equal to about one in three cases. He believed his results were as good as those of most practitioners. He had no death which could in any way be attributed to the use of instruments, and no unusual number of cases of laceration of the perinaeum, flooding, etc. In respect to hæmorrhage, in 12 cases of a series of 151 labors, serious hæmorrhage occurred; in three of these cases forceps were used, but in each case for exhaustion, inefficient pains, or tedious and difficult labor. In the 92 forceps cases there were 53 male children (58 per cent.), and 39 female children (42 per cent.). In 19 cases (20 per cent.) the occiput was posterior, — 11 male children and eight female.

Dr. Minot had often incised the thin edge of the perinaeum during delivery, in primipara, but, judging by the cases recorded in his notes, without much benefit, — in many instances it did not prevent a tear in the median line, sometimes to a considerable extent. In the treatment of hæmorrhage after delivery he desired to call attention to the fact that it was rarely fatal, and that the large number of remedies which were thought to be successful showed that probably the condition was not much influenced by any of them. He was accustomed to rely much on compression of the aorta, which was easily done, and, he thought, very efficient. Two cases, in which alarming symptoms had followed the employment of carbolyzed vaginal douches

during convalescence after labor, had convinced him that that proceeding was not safe, and where there was any fetor of the discharges he preferred the use of a swab dipped in a carbolic solution. Of course in the great majority of the forceps cases the head was on the perineum, and the instrument was used to prevent a tedious, and as he believed, useless delay.

Dr. W. L. RICHARDSON said that he had frequently observed a tendency to post-partum hemorrhage follow the use of ether. In his own practice he very rarely used ether and had never seen a case of post-partum hemorrhage. During the first stage of labor he almost invariably gave hydrate of chloral in fifteen grain doses every twenty minutes until the patient had taken forty-five grains, and thus he was able to avoid the use of ether. The uterus was, as it were, a hollow muscle, and he could not understand why ether should not tend to a relaxation of that organ as well as any other muscle of the body. He agreed with Dr. Minot as to the advantage of the frequent use of the forceps, for by their use not only was suffering prevented, but he believed that the subsequent convalescence was shortened and that we were able the better to protect the perineum from injury. He was especially interested in the case reported by Dr. Green in which the occiput had presented posteriorly. He thought physicians made a great mistake in contenting themselves with making out the presentation without also ascertaining as early as possible the position. In cases in which the occiput presents posteriorly we should remember that there is a danger of the head becoming extended. The application of pressure, as in Dr. Green's case, on the anterior part will promote flexion and thus allow of the subsequent rotation of the occiput forward. In several cases which he had seen in consultation he had been able, where pressure on the anterior part of the head had failed, to flex the head by the application of the forceps applied with the curve reversed. On examination of statistics he had been struck by the large number of cases of septicaemia which had followed the birth of a putrid child. He had therefore, the last few years, been in the habit, at the Boston Lying-In Hospital, of always using intra-carbolized injections after the birth of a putrid fetus. The results had been the avoidance of the high temperatures which had followed such confinements before the use of such injections.

Dr. REYNOLDS remarked that the paper just presented was certainly very interesting evidence of the valuable lessons which even a limited number of obstetric cases afford, when analyzed with the intelligence and thoroughness of detail which characterize this communication.

Dr. Reynolds did not admit that there was any danger of hemorrhage from ether provided the ether was administered with ordinary discretion, and said that he would weigh the strain upon the mother's system which the unrelieved suffering of labor induces very willingly against any supposed relaxation of the uterine fibre that the suitable use of this anæsthetic brings, as a factor of equal importance, if not greater, in the causation of hemorrhage. It was a matter of fact, that while only very rarely witnessing labor of any length without anæsthesia, he had not in private practice frequently occasion to observe serious hemorrhage. He believed that in the private exercise of obstetrics careful management of patients, in such particulars as the husbanding of strength and its increase before confinement, watch-

ful supervision of the process itself, and avoidance of too early departure after the delivery, would greatly diminish the chance of bleeding. After any free use of ether he was glad to administer a moderate dose of ergot, provided the uterus had first been wholly emptied.

Dr. Reynolds then said: "The importance of Dr. Richardson's remarks as to the early detection and treatment of loss of flexion in cranial presentation, where rotation will later tend to bring to the front of the mother's pelvis the frontal end of the cranium, instead of the occipital end, must be admitted; but when this subject comes up for discussion it is always desirable to emphasize very strongly the distinction between a mere posterior variety of either left cranial position or right, and such a variety when combined on the other hand with loss of due flexion. In the former case there is no interference with the normal mechanism, if we accept the possible loss of a few additional minutes while the occipital end traverses three eighths of the pelvic circle, instead of the shorter space. In the other instance, where flexion is greatly diminished, and where on digital examination the posterior fontanelle can only be reached with great difficulty, or not at all, everything presages a difficult expulsion, that perverse rotation which will bring the frontal end of the cranium to the front wall of the pelvis, and a probable emergence of the occiput backwards, over the perineum. The greatly increased suffering which this result creates, and the risk of injury to the mother, should always be borne in mind by the attendants. Here, as in so many thousand other obstetrical embarrassments, thoroughly good care involves on the part of the accoucheur presence during the earlier hours of labor, and a mind ever watchful and alert.

Two instances of adherent placenta were hardly to be expected in so small a number of obstetric cases. In one of them the existence of syphilis, a very sufficient cause, is noted. There is no evident reason for questioning the existence of real adherence in the remaining patient. True adhesion of the placenta to the uterine walls bears but an insignificant proportion to that great number which we find in obstetric reports, the majority of these latter being undoubtedly explicable as simply the sticking of the placental surface against the uterine wall, much as a man's boot sticks when he has trodden ankle deep in clay."

#### ANTISEPTIC INJECTIONS; BORACIC ACID AND CARBOLIC ACID.

Dr. CHARLES WILLIAMS spoke of the use of a saturated solution of boracic acid in the treatment of affections of the conjunctiva, and suggested its use in place of carbolic acid for injections after child-birth.

Dr. WAIREN, commenting on the dangers which are supposed to have arisen from the use of carbolic acid for injections, remarked that the tendency of surgeons was at present to use weaker solutions and to avoid using carbolic acid for washing out internal cavities, as the bladder. He also said that he had used boracic acid as an injection for the bladder.

As illustrating further the danger sometimes arising from vaginal injections, Dr. DUE mentioned the following case which had recently occurred in his practice:—

The patient was a multipara, and the labor had been

perfectly normal. Vaginal injections of carbolic acid, one part to 120, had been ordered to be given three times a day. On the morning of the sixth day, as the nurse was giving the injection, the patient remarked that "she had thrown the water up to her stomach," and immediately complained of abdominal pain, which soon became intense and attended with a condition of semi-collapse. I saw her three hours later. Her countenance was very pale, pulse weak and thready, abdomen distended, tympanitic, and very sensitive on percussion. The pain had considerably abated. Stimulants, morphia, and hot applications to the abdomen were ordered, and on the following day the pain, distention, and tenderness of the abdomen had disappeared and no ill results followed.

#### CONTINUED VOMITING OF TWIN PREGNANCY.

DR. DOE referred to the case reported by Dr. Green of continued vomiting in twin pregnancy, and asked if it had been the experience of members present that the vomiting in twin pregnancies was more persistent and intractable than in single pregnancies. Such had been his own experience.

DR. MINOT said that he had not had the same experience as Dr. Doe, for that the severe cases of vomiting which he had met with were with single children.

DR. GREEN remarked that it seemed to him very probable that the nausea and vomiting so common in the early months of pregnancy were due to the sinking of the uterus in the pelvic cavity, and that therefore it was reasonable to expect a greater intensity of these symptoms in twin pregnancy when the uterus is naturally heavier.

DR. FIFIELD reported two cases of

#### STRANGULATED HERNIA

which he had operated upon, and remarked upon the greater success which he had lately obtained in this operation, being probably due to closely stitching the hernial sack in its whole length and then closing the outer wound.

#### PERITONITIS AND PLEURISY.

DR. MINOT reported the case of a married woman, twenty-two years old, who entered the Massachusetts General Hospital January 14th and died January 21st. She had left the Lying-In Hospital in good condition, on the 8th, a fortnight after her labor, which was quite normal. Returning home she kept about house, did some washing, and hung out the clothes January 10th. While doing this she made a misstep, and thought she "strained herself." Pain in the hypochondrium followed, and was severe enough for her to go to bed. There was no chill and no cough. The pain extended over the abdomen and was followed by vomiting and diarrhoea. On entrance, four days afterwards, she seemed almost moribund, with involuntary discharge of urine. The mind was clear. There were symptoms of general peritonitis. The uterus seemed normal. On the 17th there were signs of pleurisy on both sides, and also moist bronchial râles. In the upper part of the right lung fine crepitant râles and bronchial respiration between the scapula and the spine were heard. Each expiration was accompanied by a slight groan. There was a dark, circumscribed flush on each cheek, with general cyanosis. The urine was

albuminous, but no blood nor casts were found; chlorides not much diminished. There was slight delirium the night before her death. The temperature rose steadily from 103° F. the evening of her entrance to 107.6° F. shortly before death, which was on the eleventh day of the disease.

DR. FITZ described the appearances found at the post-mortem examination, stating that they consisted chiefly of a general fibrinous peritonitis and pleurisy. The latter was double, the more abundant effusion being present in the right chest. The uterus was normally involuted, the lining membrane shreddy and injected, without offensive odor. The connective tissue of both broad ligaments slightly infiltrated with pus. The vagina and ovaries showed nothing abnormal. There was granular degeneration of the heart, liver, and kidneys. A reddish thrombus, some five inches in length, and centrally softened, extended towards the heart from the bifurcation of the inferior vena cava to the posterior wall, to which it was internally adherent.

DR. REYNOLDS said that the specimen was especially worthy of notice, as illustrating the development of general puerperal disease of grave import by extension along the connective tissue, in contrast to that which results from absorption of septic material through the inner surface of the uterus. It was well known that the latter order of sequences is thought by many of the best obstetrical authorities to be far more exceptional. The bearing which facts of this nature have upon our certainty of giving relief by intra-uterine antiseptics is evident.

In this very important and interesting specimen the surface of the uterine cavity showed to the unaided eye, at least, little evidence of the existence of pathological change. It is in the connective tissue of the broad ligaments that we see the beginning of the disease, which subsequently extended itself in the sub-peritoneal connective tissue to nearly every point of the abdominal cavity, and then developed itself still farther within the thorax. It was not now in our power to fix with accuracy the initial point from which the tissue in question was invaded. That point may have existed in some laceration at the level of the cervix; it was more probably a torn surface in the external parts, the labia or the perineum.

It was of course out of our power to exclude the surface of the uterine interior as a possible medium of septic infection in any given instance, so that the cleansing of the cavity for the chance of relief which this undertaking involves may often be obligatory, when at the same time a failure to obtain the desired improvement may be the necessary consequence of the fact that the poison was introduced through a different channel.

#### FETUS OF TEN WEEKS.

DR. C. M. GREEN showed a beautiful specimen of a fetus at about the tenth week of development. He had seen the woman five days before suffering with much nervous disturbance and in poor general health. She had weaned her first child in November, 1881, and had not menstruated since that time. The uterus was somewhat enlarged, and the os slightly patent. It was learned that the woman had believed herself pregnant, and had passed a knitting-needle presumably into the uterus; hæmorrhage occurred from time to time, and January 24th she aborted.

# PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, SECRETARY.

DECEMBER 31, 1881. Meeting called to order at 7.45. Sixty members present. Dr. R. M. HODGES in the chair. Dr. MORTON PRINCE read a paper entitled, —

## IS ACUTE TONSILLITIS A CONSTITUTIONAL DISEASE.

Vide page 96 of this journal.

Dr. E. W. CUSHING, in opening the discussion, spoke as follows: "I have been much struck with the fact that so little mention is made of this question in medical literature, as shown by Dr. Prince. The confusion on the subject is owing to loose and inaccurate diagnosis. It is pretty conclusively shown that an affection of the tonsils occurs with chill, fever, and general symptoms; infectious, epidemic, with a period of incubation, and as a rule occurring but once. These characteristics entitle it to rank as a constitutional affection, — a germ disease, as we should call it nowadays.

"It is distinct from diphtheria on the one hand, being more asthenic, with more fever, and less affection of the glands, and no patches except on the tonsil. The exudations, however, are very often quite similar to those of diphtheria, spreading between the individual follicles and pretty firmly adherent. It is very often called diphtheria, especially by our erring brethren of a certain school of medicine, and great glory is claimed for carrying a whole family through diphtheria without a death!

"Cases do occur, however, in which a diagnosis from inspection is very difficult, and if pronounced diphtheria and treated as such the error is unscientific rather than injurious to the patient.

"The disease is equally distinct from pharyngitis and common superficial or phlegmonous anginalitis, which, as every one knows, result easily and repeatedly in certain individuals from exposure to cold, wet feet, etc.; are not contagious nor epidemic, although in some rare cases there are patches on the tonsils. Follicular tonsillitis is frequently associated with bad drainage, and escape of sewer gas into the house, as remarked by Dr. Stickney, and in such cases is to be attributed to some organized living contagium, carried in the gas, and not to merely chemical or irritant local effects thereof. Isambert ascribes the disease to the darts of diathesis and considers it as a herpes of the throat, but he is probably speaking of another affection under this name. In effect Dr. Prince seems to have shown that there is a constitutional disease, epidemic, contagious, self-propagating, self limited, occurring as a rule but once. This may properly be called follicular tonsillitis or anginalitis, but not every affection ordinarily so called belongs to this class. The nomenclature and diagnosis of such affections are uncertain and confused."

Dr. T. A. DE BLOIS followed: "I wish to say a few words in support of my opinion, as well as that of many others, that acute follicular tonsillitis is not a constitutional disease. In the first place the disease confines itself to one or both of the tonsils, seldom implicating the pharynx, never the larynx nor trachea. That the onset of the disease is accompanied by a certain rise in temperature is true, but it is no more than is present in local inflammations of other mucous mem-

branes. This fever soon passes away, and the pain and discomfort incident to the tension due to blood pressure may be promptly relieved by scarification, so that it does not seem possible that any more than the gland under consideration can be involved.

"The general malaise may be easily accounted for by the interference with respiration and deglutition, and the altered secretion of the tonsils, changed from a clear fluid to a thick, sticky mucus.

"The cause of this affection can generally be traced to some local irritation — as from cold or irritating gases; the air of the dissecting-room being a prolific cause. The swallowing of caustic substances may, according to McKenzie, cause tonsillitis — thus, on good authority, we may produce a constitutional disease at will by local means.

"There are certain conditions of the body, which, though they have nothing whatever to do with the disease, yet by their debilitating influences render the part more susceptible to the local irritation: constitutional delicacy, the strumous, gouty, or rheumatic diathesis, or chronically enlarged tonsils, previous attacks, etc., may be mentioned among the predisposing causes, as La Segue states in his *Traité des Angines*: 'It is entirely local, and acknowledges for a cause the antecedent inflammation, and will itself in the future be the frequent cause of a series of relapses.' Bosworth states, 'As in all diseases of the mucous membranes characterized by fibrinous exudation, the onset of the attack is marked by a chill or decidedly chilly sensations followed by a fever more or less active in character. The cause of the affection is taking cold in the majority of cases, and yet behind this there is generally some predisposing cause of which we are ignorant.' He states again: 'Guaiac exercises a controlling influence in quinsy and this would seem to afford evidence of the truth of the view which regards quinsy as a manifestation often of a rheumatic diathesis. On the other hand, the whole subject of a special diathesis as governing the development of throat diseases rests on such uncertain clinical observation that it seems to me that it only serves to confuse, and that we obtain a clearer understanding of them by ignoring it, and regarding these affections as purely idiopathic and local.'

"One more point which weakens the constitutional side of the argument is the generally received law that one attack of a constitutional disease affords a certain amount of immunity from subsequent ones, as we see in diphtheria; but so far from doing so, one attack seems rather to pre-dispose to a second.

"I cannot conclude better than by quoting from a clinical lecture of Professor Jacobi's." Vide page 605, vol. cv., of the JOURNAL.

Dr. BUCKINGHAM said that it was impossible at present to deny or accept Dr. Prince's proposition on account of the great difficulty which often occurred in making a diagnosis; this rendered the statistics untrustworthy. Dr. Buckingham often found it impossible to make a diagnosis at first. He believed the possibility of introducing a probe into the opening of the follicles the only sure differential means at our command.

Dr. F. G. MORRILL declared his belief in the affirmative of the question, and cited several cases where the disease had apparently been caused by imperfect drainage.

Dr. H. I. BOWDITCH spoke of the great importance of investigating the different varieties of sore throat;

he believed the diagnosis of throat affections was yet in its infancy.

DR. HODGES, in closing the discussion, said that some of the obscurity which attaches to the etiology of the class of diseases under discussion appeared to grow out of inexactness in the use of words. The generic name "sore throat" includes many kinds and degrees of soreness in the different structures of the throat, and almost inadvertently a confused variety of affections are discussed in speaking of the causes of any one of the wide range of diseases embraced under this single comprehensive name.

At one end of the gamut, for example, there is a parenchymatous form of tonsillitis, attended by great swelling, sometimes extending beyond the limits of the gland itself, with an amount of inflammation so great in many cases as to lead to suppuration, or even sloughing,—and from this extreme we run down through forms of localized follicular tonsillitis, provoked by the irritation of accumulated sebaceous or cretaceous matter in the follicles of the tonsil; inflammation of different parts of the fauces, especially the uvula, the main feature of which is edema; pharyngeal folliculitis; various conditions involving the epiglottis, the vocal cords, or other parts of the larynx, chiefly marked by the symptom of hoarseness; until we come to that variety of sore throat, the characteristic of which is pain and painful swallowing, bad enough for a physician to be sent for, but with no signs of any inflammation, the parts presenting their habitual appearance, it being, in fact, a *throat-ache*, comparatively of short duration, occurring only in patients who are "run down," and disappearing with rest and good feeding.

As these and others of the varied forms of "sore throat" seem to be especially common in this city, particularly in childhood, the tendency to them diminishing towards manhood, it is desirable to keep within the limits of each individual form when questions as to their cause or pathology are being considered. This it is not easy to do; and the suggestive manner in which the subject has been presented by Dr. Prince is as interesting as it is valuable.

DR. H. J. BARNES read a paper entitled *The Water Supply of Boston*.

vide page 78 of this JOURNAL.

DR. H. I. BOWDITCH reported three cases of thoracentesis, where only a slight amount of bloody fluid had been evacuated. Dr. Bowditch stated that in his experience this condition had always been associated with cancer. (The cases will be published in full.)

DR. DAVID HUNT showed a beautifully perfect human embryo about four mms. long, with the membranes also very perfectly preserved. Its age was estimated to be about twenty-eight days.

## Recent Literature.

*Lectures on Electricity (Dynamic and Franklinic) in its Relations to Medicine and Surgery.* By A. D. ROCKWELL, A. M., M. D. New York: William Wood & Co. 1881. Pages viii. and 122.

This little book contains eight lectures, of very unequal lengths and merit, in which are considered the relations of electricity to physiology, diagnosis, and therapeutics, preceded by one on electro-physics.

The seventh lecture, on treatment of special dis-

eases, is the longest, and, so far as it goes, is generally satisfactory, but it is not possible to condense into thirty pages all that is important in the treatment of diseases by electricity. To many the narration of a few cases will add to the interest of this part of the book by giving a practical character and a little animation to the text, but the space thus used might have been utilized to greater advantage by giving more details as to treatment in certain diseases which are too briefly noticed. The section on treatment of diseases of women is well worth attention. In the various forms of catamenial disturbance electricity can be used with advantage, and it is well to have the attention of the profession called to this. The statements in regard to the use of electricity in hemiplegia of cerebral origin are good and true. In infantile paralysis the author advises faradization when the muscles respond to the faradic current. As a rule the galvanic current had better be used from the beginning.

The lecture on electro-diagnosis is only two and a half pages long, and is unsatisfactory. There are several samples of careless writing; on page 19 occurs this: "When the electrodes are applied to a nerve, and the current closed, we observe a momentary contraction." There is nothing to show what contracts. Of course it is meant that the muscle connected with the nerve contracts.

Again, on page 15, near the bottom, it is said: "By putting a bar of soft iron or a bundle of iron wire within the primary coil, the current becomes very much strengthened, and in this way the momentary action of the current, as it is closed, causes the iron bar or wires to become magnetic." It is not because the current is strengthened that the bar or wires become magnetic.

A very good *résumé* of Franklinic or static electricity is given in the fifth lecture, and the author describes very fully his method of general faradization and central galvanization in the fourth lecture. The last lecture is devoted to electro-surgery.

The book, as a whole, seems to be incomplete, and not so satisfactory as could be wished. There are many engravings, which add little or nothing to the value of the book. More care in writing and a little more space devoted to several subjects would have made a better book; if, however, one desires a brief account of electricity as used in medicine this volume will furnish much information, and can be followed with safety.

*Handbook for the Ship's Medicine Chest.* Washington. 1881.

This book has been issued, under the official authority of the Marine Hospital Service, as a means of furnishing information, in a more satisfactory manner than has heretofore been done, to masters of vessels belonging to the United States mercantile marine. It is succinct, practical, and clear. It does not fill the place of the medical man, but furnishes a very good substitute for him in places and under conditions where his services cannot be commanded. The contents are classed under the heads, Prevention of Disease, the Examination of Seamen, the Medicine Chest, Accidents, Diseases, and Extracts from the Regulations of the Marine Hospital Service. Coming, as it does, from the most competent medical authority, it cannot fail of receiving confidence.

F. H. B.

# Medical and Surgical Journal.

THURSDAY, FEBRUARY 2, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,

NO. 4 PARK STREET, BOSTON, MASS.

## CONTROL OF DEFECTIVE SIGHT ON LAND AND SEA.

IN our number for March 10, 1881, we called attention to the great looseness of the bill reported by the Railroad Committee of the Massachusetts Legislature in reference to examinations of employees for defective sight and color-blindness. The *Boston Daily Advertiser* quoted our article and added: "The JOURNAL is quite right, and it will probably find the strongest support among those railroad men who have been examined by specialists." Moreover, the experience of Connecticut and several European states shows that an examination for color-blindness is not worth much unless it has been conducted by a specialist, who consumes perhaps a minute in making it. In the bill the words "some competent person" should read "a responsible ophthalmic surgeon."

The bill, however, was passed as reported in this respect, and experience has shown our criticism to be correct. His Excellency, the Governor, even called attention to it in his inaugural as follows: "Both in justice to railroad employees, and for the safety of the traveling public, it should be provided that the examination for color-blindness and other defective sight required by the act of last year be made by persons whose competency is beyond question. The statute is too loose in this particular." The Governor and Council, as president and directors of the Troy and Greenfield Railroad and Hoosac Tunnel, had opportunity of seeing the working of the present law, which is now referred to the railroad committee for reconsideration. We would again call attention to the act proposed to them last year, as also to the one for an inter-state commission, to agree upon what was fairly required of employees engaged in moving trains, in respect to their power of sight and color sense, and standard methods of testing these by those competent to do so. These and the arguments of the professional gentlemen supporting them may be found in detail in the *Boston Herald Supplement*, February 26, 1881.

November 9, 1880, the Council of the British Ophthalmological Society appointed a committee, "To consider defects of sight in relation to the public safety, with authority to communicate thereupon with the government on the part of the Society if they should think fit." As we stated in our number of May 5, 1881, sixteen examiners reported testing 16,131 males and 1,657 females, finding among the former 4.16 per cent. color-blind and among the latter 0.1 per

cent. only defective in chromatic sense. The full report is now in the first volume of the Society's Transactions. It must be remembered that medical gentlemen in England, especially those connected with railroads, greatly doubted the results previously obtained by the few experts at work in this country. This report, therefore, must be very gratifying to the latter, as it wholly substantiates their statements.

We have not room to quote from this extremely practical report more than the following as supporting our position as to expert testing:—

"Your committee becomes more and more convinced that a competent examiner is not made in a day or even in a month, and that, even with large experience, much judgment and capacity are needful to interpret rightly the acts of the examined. This necessity is perhaps most strongly exhibited in the case of intelligent persons who are incompletely color-blind. Such persons, though they may have a much feeblér appreciation of the difference between red and green, for example, than is normal, may, after accurate observation and comparison, separate the red skeins of wool from the green. When tested, however, at various distances with colored lights their defects are startlingly apparent, and it becomes clear that they are totally unfitted for responsible posts, in which rapid appreciation of color at a distance is required." The committee close their report by saying, "The relation of the subject matter of this report to the question of the preservation of life in traveling cannot fail to impress itself upon every one, but it has been thought expedient that our statement of the subject should end here, leaving to a future time the discussion of its practical bearings in relation to the use of colored lights in signaling, both by land and sea."

In our editorial of a year ago we complained of the Massachusetts bill as not calling for *any* definite standards, either as to methods of testing or requirements, and said that this was so important that a royal commission in Belgium, in an extended report to the government, urged the forming of an international commission to decide these points for the countries of Europe in general. The bill then in Congress to initiate a similar international commission for the ocean was not reached before adjournment. This commission has since received the endorsement of many medical and scientific societies, for instance, of our Massachusetts Medical Society at the Centennial Meeting. Among the resolutions adopted by the International Medical Congress, London, 1881, as to "tests of sight suitable to be enforced in the case of signalers and look-out men, and other persons by land or sea, with suggestions as to international arrangements for a uniform system of maritime, coast, and harbor signaling, with a view to the safety of life and property" are the following:—

"(7.) That the examinations should be conducted by persons of recognized competency, under the direction of a central medical authority in each country.

"(8.) That an international commission should be constituted to fix upon such further measures as to signals as may be necessary for safe navigation, and,

specially, upon the standard colors and the sizes of the signals employed.

"(7.) A central medical authority is requisite to insure the perfection of the system and its uniformity. He should propose the examiners, and be responsible for their fitness. They should be men of ascertained competency, and, as far as practicable, qualified as medical specialists.

"(8.) The measures recommended in Articles 2 to 7 should be brought into operation without delay. But an international commission would still have to determine the precise color of the glass, securing uniformity in that as well as in the size and disposition of the signal lights.

"The Congress lay the greatest stress upon the appointment of this commission in respect of marine signaling, as quite indispensable for the attainment of the object in view. The commission would have to inquire into and decide upon many matters on which information is at present incomplete, and regarding which only a few points have been touched upon in Article 8.

"Every government, especially the maritime governments, should be requested to place one or more members on the commission, and chiefly experienced naval officers and medical specialists.

"It is understood that this question of an international commission is about to be submitted to the legislature of the United States of America, supported by a petition largely signed by scientific men of that country."

The resolutions emanated from the Ophthalmological Section of the Congress, and were drawn up, in the first place, by a committee representing twelve different countries.

Bill No. 24, House of Representatives, Washington, 1882, introduced by the Hon. B. W. Harris, of Massachusetts, chairman of the naval committee, authorized the President to initiate this commission. It was referred to the naval committee, and considered by them January 23d. If, as before, a favorable report is made, and Congress will pass the bill, our government will have one of the few opportunities of leading in scientific matters. If Congress refuses, no money will be saved, as the United States could not decline to take part in an international commission of such importance, which England will inaugurate, and take, naturally, the honor of having so done.

#### ANNUAL REPORT OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE FISCAL YEAR 1881.

DURING the year ending June 30, 1881, 32,613 patients received relief from the Marine Hospital Service of the United States, showing an increase of numbers of 7,753 seamen treated over the year preceding; 309,596 days' relief in hospital were furnished. The volume gives evidence of earnest and good work by the medical men in this important branch of the government. The receipts from hos-

pital dues and other sources were \$386,059.81, and the net expenditures \$100,101.06.

Of eighteen candidates who applied for admission to the medical staff, out of thirty applicants, two passed the board and were appointed assistant surgeons.

The furnishing of hospital and office relief to persons not sailors, or to sailors not rightly entitled to relief, occasionally happens, notwithstanding the great care exercised by medical officers at the various stations. Two convictions were made by the courts during the year, under the statute providing a penalty for frauds against the government, and other suits of a similar character are pending.

The physical examination of seamen, which has been looked on as so important a means of securing able men to man our vessels, is again, as it should be, impressed on the attention. While the evil exists of sending vessels to sea manned by incurable syphilitics, chronic invalids, and even lunatics, it is presumed that the legal remedy is not beyond reach, or its ultimate application altogether hopeless. Crews are openly sold, like cattle, in all our great ports, blood-money men control the sailor market, and advance wages work a great detriment to our commerce. All efforts to control the matter have been, thus far, rendered unavailing by combinations of sailor landlords and shipping agents.

A draft of a bill for the encouragement of American seamen and to provide for a National Snug Harbor is preceded by a memorandum giving important information regarding vital points in the conduct of the service.

The volume closes with statistical tables, reports on the sanitary condition of the stations at Portland, Me., and at Mobile, Ala., and with a full and well-written article on Beri-Beri. Eighteen cases of this disease — the first recognized in this country — were treated by Surgeon Hebersmith in the Marine Hospital at San Francisco. The seamen were landed from the Brazilian man-of-war *Vital de Oliveira* in August, 1880, while on an official voyage round the world. Cases of diarrhea, dysentery, asthma, and bronchitis, in addition to beri-beri, had called attention to the condition of the vessel itself. This was found to be poor in the extreme. An ill-arranged and poorly-ventilated berth-deck gave less than fifty cubic feet of air-space to a man, and a direct communication was found to exist for the passage of foul air between the hold and bilges and the quarters of the men. The vessel was without proper food and vegetables, not even potatoes being provided; no liquid stimulants or lime-juice or woolen clothing. Twenty-one cases were landed at San Francisco, of which eighteen were of beri-beri, uncomplicated, and one of phthisis and beri-beri. Fifteen cases of the latter disease recovered. Many of the physicians of San Francisco saw the cases and took part in its study, making microscopic specimens and sphygmographic drawings. Dr. Hebersmith epitomizes the various views regarding the disease as indicating it to be primarily and essentially a blood-poisoning, a zymotic disease, with increase of the white corpuscles, and a swollen or bursting, shriveled or

stellate, appearance of both the red and white corpuscles. These morbid appearances disappeared as the disease progressed to recovery, and were taken as an index of the progress of the disease. The pulse in this affection is high, the temperature low, and it was early observed that the two phenomena gave no adherence to the usual rules of pathology; pulse and temperature bore no relation to each other, for frequency of the former with lowness of the latter was the rule rather than the exception. Looseness of the bowels was observed in eleven of the cases. There was found to be uniform cardiac effusion. Seven patients presented an oedematous condition of the abdomen or extremities. The principal symptoms, indicating lesions of the nervous system, were confined to the lower extremities, the local anaesthesia appeared in the early stage, and at subsequent stages the ataxic gait and tendon reflex. The appetite was largely increased. Food, tonics, wine, and pilocarpin were used in the treatment. A detailed clinical record, with reports on the microscopic examination of the blood, and official reports from Ceylon and other places in the East Indies, complete the record.

#### MEDICAL NOTES.

— Five small-pox patients are now in hospital at Canterbury Street. The Board of Health have opened new stations for vaccination in some of the most crowded portions of the city.

— A petition to the following effect has been presented to the Massachusetts Legislature and referred to the committee on Public Charitable Institutions:—

That the rights and needs of persons who are actually insane, and of those who are charged with being insane, are not sufficiently protected by our law. Your petitioners believe that the condition of both these classes would be much improved by a law creating a Commission of Lunacy of one or more persons, whose duty it should be to watch over and protect those who are confined in lunatic hospitals and other places, and to suggest improvements in the laws regarding the insane and the regulations of hospitals for them. Such commissions in England and Scotland have proved exceedingly useful, and are urgently needed in Massachusetts.

Your petitioners, therefore, urge the passage of a law creating a separate Lunacy Commission.

— In the Massachusetts Senate an order was adopted recently, on motion of Mr. Crocker, of Suffolk, that the Committee on Public Charitable Institutions consider the expediency of discontinuing the State Board of Health, Lunacy, and Charity, and creating in its place separate boards; in other words, of annulling the present awkward arrangement. The Legislature may not find it expedient, for various reasons apart from the merits of the case, to take this step this year. But that an expediency which is already so manifest will before long enforce action there can be very little doubt.

— Were the interest in the efficiency of a State Board of Health among the members of the Massa-

chusetts Legislature as great as the importance of the subject and the welfare of their constituents would seem to warrant, we suppose the above resolution in the Senate would have been referred to the Committee on Public Health as well as to the Committee on Public Charitable Institutions.

In this connection our readers may like to know the names of the gentlemen composing these two committees, and we therefore print them:—

*Public Charitable Institutions.*—Messrs. Winship of Middlesex, Hastings of Worcester, and Mudge of Essex, of the Senate. Messrs. Burt of Boston, McSorley of Cambridge, Leonard of Boston, Tapley of Danvers, Roberts of Salisbury, Dr. Holbrook of Palmer, Ayres of Hadley, and Dr. Babbitt of North Adams, of the House.

*Public Health.*—Messrs. Horton of Essex, Tirrell of Middlesex, and Ingalls of Worcester, of the Senate. Messrs. Dr. Wilson of Boston, Rand of Medford, Hamlin of Boston, Dr. Harris of Arlington, Dr. Hodgkins of North Brookfield, Dr. Campbell of Boston, Smith of Andover, and G. D. Chamberlain of Cambridge, of the House.

— The State Board of Health of New Hampshire has issued the following circular:—

The National Board of Health has just declared small-pox to be epidemic in the United States. Considering its alarming prevalence, and the fact that it has already invaded nearly every State in the Union, ours thus far being an exception, we desire to spare no effort in our exertions to protect our citizens from its infection. To this end, should a case make its appearance within your locality or knowledge, within the State, you are requested to telegraph this office at once of the fact, and we will take such immediate action as the exigencies of the same demand.

— It is intended to attach to the iron railing in the London Post Office yard a weather-proof case containing a stretcher, splints, tourniquets, roller and triangular bandages, lint, and other useful appliances, all of which will be kept in readiness for immediate use in case of emergency.

— According to the *British Medical Journal* of January 7th there were thirty-two deaths from small-pox in London during the preceding week.

— Sir Erasmus Wilson has expended £30,000 in the erection of a new wing and Chapel to the Margate Sea-Bathing Infirmary.

— Dr. Robert Saundby uses inhalation-respirators for antiseptic inhalations in phthisis and finds them of service to many patients in checking purulent secretion and allaying cough. The *British Medical Journal*, December 21, 1881, contains two cuts of the forms of inhalers used.

— The death is reported of Dr. Jonathan Leonard, a much respected practitioner of Sandwich, and member of the Massachusetts Medical Society, at the ripe age of seventy-seven years.

— Professor Charcot has been recently transferred, at his own request, from the chair of pathological anatomy to a professorship of nervous diseases recently established by the Faculty of Medicine at Paris.

## Miscellany.

### NEGLECT OF VACCINATION; A STATE VACCINE ESTABLISHMENT.

THOSE who feel that vaccination as practiced to-day does not rest upon a basis of fact and observation sufficiently free from question to commend it to the full confidence of wise and thoughtful men, to say nothing of the ignorant and foolish, will find in the article on Neglect of Vaccination; How Shall We Treat It? by Dr. Z. B. Adams, of Framingham, in the last supplementary report on health of the health department of the Massachusetts Health, Lunacy, and Charity Board, a suggestion for the establishment of a State Vaccine Institution.

We make the following extracts from the closing pages of Dr. Adams' paper, feeling that his suggestion is in itself a good one, and though unprepared to express any opinion as to its practicability think it more likely to be realized as a National than as a State institution.

"After all, nothing will justify legal interference, nothing will satisfy common sense or scientific inquiry, like the assurance that vaccination will protect. Probably there will always remain a small fraction of mankind either insusceptible of vaccinia, or in whom it affords no protection against small-pox. Common sense will make allowance for this; science may perhaps restrict the number; while law is made for the general and not for the particular. It remains for art to secure for medical science, as far as possible, this certainty of protection, if we would prevent vaccination from falling into disuse, and perhaps contempt. The following plan seems feasible and likely to succeed.

"(1.) A State vaccine establishment, the chief business of which shall be to propagate vaccine lymph by animal transmission, or perhaps by artificial methods (as Mr. J. Lawrence Hamilton of London proposes), and from which all the physicians in the State shall be supplied. This lymph must be proved by constant testing; and the recipient must be required to report his results, and acknowledge receipt, ten days after date. With the matter should be sent a recommendation to the physician to vaccinate, if possible, every infant born in his practice within — months after its birth; also such instructions as may best prevent imperfect vaccinations, which are the opprobrium of the system as now practiced.

"(2.) Vaccination to be forbidden by law, except by the hands of those to whom lymph is intrusted by the institution.

"(3.) Annual examination by officers of the institution, or its appointees, of the schools of the Commonwealth, with two objects; first, to secure uniformity of results, and report and tabulate all exceptional or irregular cases; second, to disclose any neglect on the part of the school committee to enforce chap. 41, sec. 8, of the Revised Statutes.

"(4.) A note of advice sent annually by the institution to the Boards of Health recommending re-vaccination of every child on reaching the age of —. This is to be enforced by the school committee, with additional legislation for the purpose if found to be necessary.

"(5.) Notice to re-vaccinate whenever the protection of public health requires.

"(6.) Notification to superintendents or other officers of incorporated manufacturing companies, etc.,

that the regulations of chap. 26, sec. 30, of the Statutes, are in force, and must be complied with.

"(7.) An annual or biennial report from the institution, to be published in the public prints, calling attention to the subject, detailing experiments, methods, and results, and mentioning towns, cities, or manufacturing corporations where neglect of vaccination is found.

"It may be that we have in the prophylactic power of vaccination the germ of a general law or principle applicable to other diseases besides the small pox. This is not proven, but not improbable. Meantime vaccination must remain a law to itself. Until a discovery is made of analogous facts in other diseases, the plan here proposed seems the true method of arriving at the principle which governs the phenomena.

"If this plan can be carried out faithfully for a series of years, we shall gain two or three points of prime importance. (1.) Many vexed problems, the solution of which science can only obtain from systematized art, will be resolved. These problems are, many or some of them, certainly capable of answer, if not of complete solution. What constitutes a perfect vaccination? and, What is the significance of the imperfect revaccination sore-arm? are among these questions. (2.) Again, we shall not have to wait for epidemics to compel us by their cruel logic to submit ourselves or our children to the practice. (3.) No one will think of shrinking, as is now often the case, from contact with small-pox or varioloid. (4.) There will be no such thing, at least in Massachusetts, as a vaccine famine, like that seen in Philadelphia, in San Francisco and Sacramento, in the midst of an epidemic. These things we may confidently hope for; but that the last word will ever be said about vaccination or small-pox, we cannot expect until the millennium."

### INTESTINAL INOCULATION FOR TYPHOID FEVER AND PHTHISIS.

#### I. TYPHOID FEVER.

MR. EDITOR, — I desire to make a few suggestions through the columns of the JOURNAL on the value of intestinal inoculation of individuals, and especially children, by causing them to swallow the germs or *matrices morbi* of typhoid disease with the object of inducing mild, continued fever, the course of which wears out congenital susceptibility to the peculiar morbid poison, and thus obliterates all liability in after life to a more fatal form of the malady, and on the paramount importance of doing the same thing as a prophylactic against and remedy for incipient pulmonary consumption, phthisis pulmonalis, and tubercular meningitis, in order to weed out and abolish the *tuberculous diathesis*.

In considering the prophylaxis of typhoid disease the prodigious importance of the subject can only be fully realized by remembering not only the current deaths from this affection in a sporadic form, but also its fearful mortality when prevailing epidemically at irregular periods in thickly populated regions.

A recent writer in this journal, who has carefully looked up the medical statistics of Massachusetts, says that during the last forty years there have been in this State alone forty thousand deaths from typhoid fever.

During the height of the epidemic of this disease, which began in Great Britain about the close of the Franco-German war, the registrar-general<sup>1</sup> reported

<sup>1</sup> Summing up by the late registrar-general published in the London Times.

thirty-five thousand deaths as having occurred throughout England and Wales within a period of eighteen months.

Surely, with such fell mortality, inoculating children and adults to prevent their having in after life this disease in the natural, as is said of small-pox, and more dangerous way, is not less important than Jennerizing, vaccinating, or, of old, inoculating individuals to keep them from having frequently formidable and often fatal variola.

To show the disabling effects of typhoid fever, and how its prevalence acts as a hindrance to procedures of all sorts, it is needless to go beyond recent years. The prevalence of typhoid fever during the Franco-German war, together with the mortality from this disease, were grave sources of inconvenience and embarrassment to the respective medical staffs, and lessened considerably the efficiency of both armies.

In the Tunis war now going on, France has been obliged to recruit her ranks by ordering numerous reinforcements to supply the place of soldiers in Africa disabled by typhoid disease.

The success of Tom Hughes' colony in Tennessee has been seriously compromised by an outbreak of typhoid fever amongst his exiled Will Wimbles; and there is hardly a town of any size in the Union from which tourists to Italy have not either suffered from or died of Neapolitan or Roman fever — typhoid.

How much better it would have been for these soldiers, Will Wimbles, and American vagrants, had they been subjected to intestinal inoculation when children with the germs of typhoid disease, and had gone through the fever in a mild form, rather than have waited to become, later in life, victims to this malady of a more unmanageable and fatal type, and under circumstances where its management and treatment in camps, colonies, and human livery-stables — hotels and pensions — must be generally of a very insufficient and objectionable character.

In cold climates typhoid fever usually occurs in winter from house poison, and when the temperature is zero F. it becomes almost impossible to ventilate the sick rooms without the risk of giving the patients cold, and the result is many die from foul, irrespirable atmosphere. Would it not be much better to inoculate for this disease, and have it over during mild, summer weather, when the patients could be freely exposed to fresh air from without?

Moreover, age has more to do than anything else with the mortality of typhoid disease, youthful patients recovering almost uniformly without medication of any sort, while those of advanced years are apt to die in spite of all that can be done for them.

Of all the specific diseases happening once, and usually not occurring again, it is only in typhoid disease that non-recurrence may be regarded as absolute, because the elements on which it feeds being exhausted, the susceptibility to the morbid poison is also worn out, and never returns, while in all the rest the materials on which they flourish are often renewed, and with their renewal susceptibility to the action of the peculiar morbid poisons returns. Who has not seen scarlatina, rubella, variola, and whooping-cough twice in the same subject?

Cazenove,<sup>1</sup> after remarking that he had repeatedly seen variola of an intense form at different epochs in the same individuals, notes, on the trustworthy author-

ity of M. Thomson, the case of an individual who suffered from six attacks of variola, but that careful observer, the late Baron Louis, saw only two instances where the individuals might have had two separate and distinct attacks of typhoid fever, and in these the evidence of a second seizure was so cloudy that he remained to the last in doubt whether any individual had ever suffered oftener than once from this affection. I have never seen typhoid disease twice in the same subject.

The non-recurrence of typhoid fever is, then, a great leading truth of prime practical importance, since it renders its prophylaxis complete, while in variola and varioloid it is at best incomplete, and merely tentative, there being a constant tendency to recurrence at longer or shorter intervals, and yet with all this disposition to repetition requiring vaccination to be repeated, Jenner's discovery, above all others, is without doubt the greatest boon ever bestowed on mankind.

The question may be asked, How is inoculation to be effected? The answer is easy. Precisely in the way milk-men have produced epidemics of typhoid fever by serving their customers milk containing the germs of this disease, and as "milk sickness" has often been caused in the Western States of the American Union by drinking in milk, water, or some other fluid, bacteria, bacilli, or some *materies morbi* too subtle for micro-copic and too evanescent for chemical detection.

I have seen only five cases, and all of these in one group, where continued fever was evidently produced by the patients having swallowed the morbid poison of typhoid disease. It was composed of four white children and a negro youth of seventeen. In all a mild typhoid fever, of the mild, adynamic type, ran the usual classic course of twenty-one days. They were all marked by the usual subjective signs, including lenticular, rose-colored spots on the eighth, and sudamina on the sixteenth day, except that no roses bloomed on the abdomen or loins of the negro, but were presumed to be blushing unseen beneath *pigmentum nigrum*. Two of the children had a look of extreme innocence, caused by a loss of power or temporary paresis of the muscles of expression; they had also relaxation of the iris of both eyes, causing the pupils to be larger, and to respond more slowly to light than those of healthy individuals placed in like situations as regards light. None of them took a particle of medicine of any kind from the commencement of the attack to the end of convalescence, which was completed in about nine days after the fevers had run their courses. Their chief diet was milk, of which they were permitted to take as much as they wanted. One asked for coffee, and was allowed to have it. They all ate daily during the entire course of the disease two or three ripe, soft, open-stone peaches, which were in perfection the middle of August. They had from three to five stools daily. During the initiative fever, lasting about seven hours, the pulses ran high, but after that had subsided they were rarely at any time above one hundred. In all pinching the biceps developed a ring, and when the pectoralis major muscles were tapped with the end of the finger cones or pyramids stood up. In none was the temperature very high, there being no such thing in any of them as the *calor mordax* of the older writers.

The history relating to the origin of these cases is an old story. A case of mild, continued fever had been carried from the city three miles to a country house, the inmates of which, five in number, none of

<sup>1</sup> Cazenove, quatrième édition, Paris, 1847, page 232.

whom took the disease, were supplied with water from a spring from which ran a small stream into which the dejections from the patient were thrown. About four hundred yards lower down on the same stream was an excavation looking like a primitive spring, the water running into it from the source above described, through and over stones, and concealed by grass and undergrowth. From this small pond a family of seven, including the five fever cases, derived its water supply.

I know of one other instance in which individuals, children and adults, must have swallowed the *matrices morbi* of typhoid disease in well-water, and yet no ill results followed, which made me question whether diseases, like plants, might not be of two sexes or something equivalent, and whether it might not be the male or female variety only which is capable of inoculating or infecting the aggregated and isolated glands of the ileum, but it may have been that the *contagium* was destroyed by the coldness of the well-water, which had a temperature of 56° F., or that the well was supplied by an underground stream, which carried off everything thrown into it.

From the preceding observations it would appear that the last endemic of milk fever in London, observed more particularly by the late Dr. Murchison, as well as all similar outbreaks of typhoid disease occurring from a like cause in Great Britain and the United States, instead of being regarded as unmitigated evils, should, on the contrary, have been looked upon as boons of unmixed good, and that it would be a great blessing for all people under twenty years of age could they in like manner, and under favorable circumstances, become impressed with the contagion of typhoid fever. Particularly homateous would this blessing be in cold climates like Northern Russia, Norway, Sweden, and the Canadas, where patients might be subjected to intestinal inoculation, and go through the morbid probation of typhoid disease during summer, when they would avoid the great danger arising from close, ill-ventilated apartments, and get inexhaustible supplies of fresh, pure air, so essential to comfort and recovery.

Very truly yours,

T. H. BUCKLER, M. D.

PARIS, December, 1881.

Deaths reported 2902 (no reports from Cincinnati and New Orleans): 1120 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 719, consumption 433, lung diseases 436, diphtheria and croup 235, scarlet fever 166, small-pox 83, typhoid fever 64, measles 49, diarrhoeal diseases 33, whooping-cough 25, malarial fevers 24, cerebro-

spinal meningitis 23, erysipelas 17, puerperal fever 11. From scarlet fever, New York 102, Brooklyn 28, Buffalo nine, Philadelphia seven, Chicago four, St. Louis and Baltimore three each, Pittsburgh and Lynn two each, Boston, District of Columbia, Milwaukee, Providence, Charleston, and Worcester one each. From small-pox, Chicago 29, Philadelphia 23, Pittsburgh 20, New York seven, St. Louis two, Boston and Milwaukee one

each. From *measles*, New York 41, Brooklyn three, Milwaukee two, Philadelphia, Pittsburgh, and Buffalo one each. From *whooping-cough*, New York 12, Brooklyn four, Pittsburgh two, Philadelphia, Chicago, Boston, St. Louis, Baltimore, Cambridge, and Fall River one each. From *malarial fevers*, New York 13, Brooklyn, Chicago, and St. Louis three each, District of Columbia and Nashville one each. From *cerebro-spinal meningitis*, Chicago five, New York four, St. Louis and Buffalo two each, Philadelphia, Baltimore, Pittsburgh, Milwaukee, New Haven, Charleston, Lowell, Lynn, Salem, and Quincy one each. From *cysticercus*, New York and Chicago four each, Philadelphia and Brooklyn two each, Boston, Pittsburgh, New Bedford, Brockton, and Marblehead one each. From *puerperal fever*, Chicago two, New York, Philadelphia, Brooklyn, Boston, Buffalo, Milwaukee, Providence, Nashville, and Palmer one each.

Ninety cases of small-pox were reported in Pittsburgh, 18 in Buffalo, 15 in Brooklyn, eight in Baltimore, five in New Haven, two in Milwaukee, and one in Boston; diphtheria 36 cases, scarlet fever 17, typhoid fever 11, in Boston; diphtheria nine, scarlet fever nine, in Milwaukee.

In 40 cities and towns of Massachusetts, with a population of 1,071,999 (population of the State 1,783,086), the total death rate for the week was 19.79, against 20.97 and 18.45 for the previous two weeks.

For the week ending December 31st, in 149 German cities and towns, with an estimated population of 7,777,635, the death-rate was 26.8. Deaths reported 4014; under five 1882; pulmonary consumption 540, acute diseases of the respiratory organs 367, diphtheria and croup 250, diarrhoeal diseases 133, scarlet fever 101, whooping-cough 65, typhoid fever 36, measles and rubella 49, puerperal fever 30, small-pox (Dresden, Essen) two, three, typhus fever (Thorn) two, Bromberg) three. The death-rates ranged from 15.1 in Potsdam to 41.1 in Essen; Königsberg 33.9; Breslau 32.7; Munich 31; Dresden 32.4; Berlin 25; Hamburg 23.5; Hanover 21.6; Bremen 18.2; Cologne 30.2; Frankfurt 16; Strassburg 35.5.

The list of large towns, of which vital statistics are given in

the first English weekly returns of the new year, has been increased so as to include all those municipal boroughs in which the enumerated population in April last exceeded 70,000 persons. For the week ending January 7th in 28 English large towns, with a population, estimated to the middle of the year 1882, of 8,455,308, the death-rate was 25.2. Deaths reported 4080; acute diseases of the respiratory organs (London) 489, whooping-cough 169, measles 145, scarlet fever 133, fever 57, diphtheria 34, diarrhoea 30, small-pox (London) 20. 24. The death-rates ranged from 13.3 in Halifax to 36.9 in Preston; Bristol 20.9; Sheffield 22.8; Birmingham 24.8; London 24.9; Manchester 25.3; Leeds 27.7; Liverpool 31.3. In Edinburgh 19.1; Glasgow 26.6; Dublin 36.

In the English towns for the week ending January 14th, the death rate was 23.3. Deaths reported 13783; acute diseases of the respiratory organs 457, whooping-cough 182, measles 129, scarlet fever 115, fever 56, diarrhoea 43, diphtheria 28, small-pox (London) 21. 26. The death-rates ranged from 14.5 in Leicester to 34.7 in Preston; Bristol 20.1; Birmingham 21.2; Sheffield 22.1; London 23.3; Leeds 23.4; Liverpool 25.9; Manchester 28.2. In Edinburgh 20; Glasgow 27.1; Dublin 35.1.

For the week ending December 31st, in the 21 chief towns of Switzerland, population 479,934, there were 26 deaths from pulmonary consumption, acute diseases of respiratory organs 24, diarrhoeal diseases eight, diphtheria and croup eight, typhoid fever three, puerperal fever two, scarlet fever one, small-pox one. The death-rates were, Geneva 16.7; Zurich —; Basle 20.1; Berne 38.4.

For the week ending January 7th, in the same towns, there were 50 deaths from pulmonary consumption, acute diseases of the respiratory organs 36, diarrhoeal diseases 20, diphtheria and croup 13, whooping-cough 11, typhoid fever four, puerperal fever four, scarlet fever 20. The death-rates were, Geneva 32.3; Zurich 27.7; Basle 28.7; Berne 28.5.

The meteorological record for the week ending January 21st, in Boston, was as follows:—

| Date.            | Barom-eter. | Thermom-eter.           | Relative Humidity. |            |             | Direction of Wind. |            |            | Velocity of Wind. |            |            | State of Weather. <sup>1</sup> |                       |                   | Rainfall. |                  |

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 21, 1882, TO JANUARY 27, 1882.

STERNBERG, GEORGE M., major and surgeon. Granted leave of absence for one month, and during his absence Surgeon J. C. Bailey to attend the sick at Point San Jose, Cal. S. O. 9, Military Division of the Pacific and Department of California, January 16, 1882.

GAUDNER, WILLIAM H., captain and assistant surgeon. Now at St. Augustine, Fla., to proceed to San Antonio, Texas, and report in person to the commanding general, Department of Texas, for assignment to duty. S. O. 11, A. G. O., January 19, 1882.

COMBLES, E. T., captain and assistant surgeon. Now stationed at Columbus Barracks, Ohio, to report in person to the President of the Medical Examining Board, in session in New York City, for examination for promotion, and, upon completion of examination, to return to proper station. S. O. 19, A. G. O., January 2, 1882.

MADDOX, THOMAS J. C., first lieutenant and assistant surgeon. Having reported at these headquarters, in compliance with S. O. 2, C. S., A. G. O., will report to the commanding officer, Fort Clark, Texas, for duty. S. O. 6, Department of Texas, January 16, 1882.

ERRATA.—On page 99 of this number, in table of Average Duration of the Stages of Labor, for Primipara read Multipara, and for Multipara read Primipara.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting of the Society will be held on Monday evening, February 6, 1882, at eight o'clock, at the Medical Library, 19 Boylston Place. Reader, Dr. W. H. Baker. Subject, Vaginal Ovaryotomy. M. H. RICHARDSON, Secretary.

BOOKS AND PAMPHLETS RECEIVED.—The Official Gazette of the United States Patent Office, containing the Patents, Trade-Marks, Designs, and Labels, issued Tuesday, January 10, 1882. Published by authority of Congress. Vol. XXI. Nos. 2 and 3.

## SOME POINTS REGARDING THE DIAGNOSIS OF UTERINE ANTEFLEXIONS AND ANTEVERSIONS.

CLIFTON E. WING, M. D., BOSTON.

PERHAPS upon no subject connected with the treatment of the diseases of women is there a greater difference of opinion among gynecologists than upon the question of the practicability of remedying the forward displacements of the womb (anteflexion and anteversion), and relieving the symptoms arising therefrom, by the use of pessaries. One class of practitioners declare all supporters useless in such cases. The other class claim most excellent results from their use; of these latter, A will be enthusiastic over one particular kind, B will declare that the instrument which he has himself devised, different from all others hitherto in use, is the only one which he has found to yield satisfactory results, and will express astonishment that C should ever have invented his particular form of supporter since it is wrong both in theory and application, while C, upon being interrogated, will perhaps express a similar idea of B's instrument as well as of that employed by A. With the existence of such differences of opinion among the uterine specialists it is no wonder that the average general practitioner is a little skeptical, at times, as to the real value of supporters in such cases.

Why is it that different practitioners hold such diametrically opposite opinions upon the subject? I believe that "error of diagnosis," or, perhaps, I should rather say, "want of precision in diagnosis," is the cause. The anteflexion or anteversion of the one gynecologist, conditions which he finds but rarely, and then has but little success in treating, is a very different thing from the anteflexion or anteversion of his neighbor who diagnosticates these displacements very often and easily relieves the great majority of them by the use of pessaries of one kind or another. Such displacements the first practitioner will also treat successfully perhaps, but he will not consider that he has had to deal with either anteflexion or anteversion.

On making a uterine examination of a woman whose womb is in its normal position, the neck of the uterus is usually the only part of that organ to be felt by the finger in the vagina, unless the pelvic parts are forcibly pressed downward by the other hand upon the abdomen (bimanual examination).

Now, if in his examination of a case, the physician's finger comes at once in contact with the body of the womb, which can be plainly felt through the anterior vaginal wall, he is apt to conclude that he has to deal with a marked case of forward displacement. Feeling with his finger a sulcus on the anterior surface of the womb, at or near the junction of body and cervix, he diagnosticates "anteflexion." Not feeling this place of flexion he settles to his satisfaction that the case is one of "anteversion." In point of fact the great majority of such cases are neither "anteflexions" nor "anteversions," but simply instances of the "sagging uterus" so-called. The subject can be made plain by diagrams.

In the first diagram the line *C D* is drawn in the axis of the uterus, which is in its normal position. The line *B A* is drawn in the axis of the vagina and indicates

the direction which the examiner's finger naturally follows. No part of the womb can be easily reached per vaginam, save the cervix. In the second diagram the position of a "sagging uterus" is shown. It will be noticed that in this position its axis is but little if any

changed from the axis of the womb in its normal position (represented by the line *C D*). But when the physician comes to make his vaginal examination, passing his finger in the direction of the line *B A*, the normal and usual direction of the vagina, he feels

(through the anterior vaginal wall and the bladder) not the cervix uteri which he expects to find in this direction, but the anterior wall of the body of the womb, perhaps near its very top, and commonly he reasons "the womb must be badly tipped forward, else I could not so clearly feel the fundus."

Now the cases of "sagging womb," at least the great majority of them, are easily relieved by the use of proper supporters, and many patients who have suffered much from such displacements, after wearing supporters for awhile, can dispense with them and have no return of the trouble. Hence we can understand how physicians who consider such displacements as anteflexions and anteversions can claim that they readily relieve these malpositions with supporters, and it does not make any difference what kind is used, whether it be A, B, or C's particular choice, whether it be simple or complex, whether it be one of the many "anteversion" or "anteflexion" devices or a common lever pessary (and the last kind being the simplest is the best of all); anything which tends to press the uterus upward and lifts its weight off the overstretched

tissues, will afford comfort to the patient, provided that it be decently fitted so as not of itself to cause pain and discomfort.

But it may be asked, How is it that a flexion can be felt at the junction of body and cervix if the case is not one of antelexion? The explanation is simple. If, as is often the case, the uterus descends ("sags") so far that the cervix rests upon the floor of the pelvis, or, more precisely, the posterior wall of the vagina, the direction of the plane of the latter is such that it tends to press the neck of the womb forward. In certain cases as the cervix is pressed forward the fundus falls backward and a backward displacement results, but in many other cases the fundus remains in its proper axis while the cervix alone is displaced from its normal direction. (See Diagram No. 3.)

Diagram No. 3

The result is the flexion which the examiner's finger detects, an "antelexion of the cervix," if you choose so to call it, but an "antelexion of the cervix" purely secondary in its nature, and which requires nothing further in the way of treatment, as the rule, than that the uterus be so lifted that its weight shall not rest upon its cervix against the posterior vaginal wall. Indeed, I think the term "antelexion of the cervix" applied to such conditions often deceives the physician as to the true nature of the case he has to deal with. Take the weight off the bended cervix, and you may be pretty sure that the latter will soon regain its normal position and axis, and that it will rarely if ever be necessary to perform "division of the cervix" with the knife in order to straighten the uterine canal, as has been done so often in the past in just such cases, and as is still advised in some of the text-books as a regular procedure. The results obtained in such cases with properly fitted supporters are usually exceedingly satisfactory. Often as complete relief from the many pains and aches which the patient suffers can be afforded as in the most marked case of retroflexion even.

Antelexion and anteversion may of course coexist with "sagging" of the womb. The conditions are often combined in the same patient. When this is the case the physician may hope to afford relief with supporters in direct ratio with the preponderance of the "sagging" over the displacement forward, but in order to form a correct opinion of his cases he must be careful and not fall into the error we have pointed out, and conclude that he has to deal with a marked forward displacement simply because the fundus is plainly felt *per vaginam*, and he must remember that with a sagging of the uterus any degree of forward displacement seems, by digital examination, much greater than it really is.

With this explanation of the conditions so often wrongly considered antelexion and anteversion, we can understand why certain so-called "anteversion and antelexion" pessaries are highly praised by their various admirers and inventors, while others, equally competent, find them anything but satisfactory for their cases. Most of these instruments are supposed to force the fundus up towards its normal position by pressure exerted through the anterior vaginal wall upon it (the fundus). But the tender bladder is in the way, lying between this anterior vaginal wall and the uterus in such cases, and it is nonsense to talk of exerting enough

steady pressure upon the anterior vaginal wall to force the fundus into position when such pressure must act through the bladder which, as the rule with such displacements, is already irritable. When any good results are accomplished by this class of supporters it is probably because they put the anterior vaginal wall upon the stretch, and, lifting it somewhat, they must also lift in a measure the womb to which it is firmly attached at the cervix, but the same result (the lifting of the womb) can be better brought about by a common lever pessary properly adjusted.

Where the uterus is displaced forward without material descent in the pelvis, a condition to which the unqualified terms antelexion and anteversion should properly be restricted, fortunately a condition which is extremely rare, we have an entirely different matter to deal with. Here I have failed to find any kind of pessary satisfactory, and can hardly say what course I may pursue in the next case which may present. Intra-uterine stem pessaries, which are best dispensed with in all other displacements, are scarcely less unsatisfactory here.

Upon looking through the text-books, and seeing how the subject of pessaries is treated in them, one familiar with their proper uses cannot but wonder that practitioners who depend upon information obtained by reading the so-called "authorities" ever have any success whatever with them. Take, for example, two books much in use, Thomas's and Barnes's. In the former is the well-known plate copied from Hewitt, in which Hewitt's anteversion pessary is represented as pressing up between uterus and bladder in an impossible way, while the pessary itself rests upon nothing. Barnes gives an equally curious diagram of the action of one of Thomas's inventions for anteversion. Here, again, the supporter floats in position sustained by some mysterious power. In both diagrams the instruments are represented as causing an amount of upward pressure against the anterior vaginal wall which in practice would seriously injure the parts in a very short time. Thomas figures (page 368, edition of 1880) the normal position of the womb with the close relations of bladder and cervix uteri, and on page 411 (same edition) an imaginary relation of the parts in antelexion, in which latter diagram there is a space of several inches between the cervix uteri and the bladder, and the same convenient space is figured in most diagrams of antelexion and anteversion pessaries in position; yet Savage<sup>1</sup> states: "The pouch of Douglas behind and the bladder in front, notwithstanding the yielding character of its uterine cellular connections, invariably follow the uterine cervix, maintaining unaltered relations with it, whatever be the nature of the displacement. This is actually a rule without exceptions, never disregarded without evil consequences."

In Barnes's work are three plates intended to show the application of a lever pessary for retro-displacement. Here, again, nothing seems to support the supporter. Two plates are given to show how an intra-uterine stem may be used to assist the lever pessary in keeping the womb in position in cases of retroflexion, when it is a fact that if a lever pessary is properly used such assistance is unnecessary.

When the leading works thus treat the subject of supporters, what can be expected of those who blindly attempt to follow their instruction?

STRAMONIUM POISONING.<sup>1</sup>

BY HERBERT TERRY M. D., PROVIDENCE.

THE thorn apple, *datura stramonium*, grows very plentifully in all the waste places about Providence, and the rarity of fatal cases of poisoning among the children is no less surprising than fortunate.

All parts of the plant are poisonous, but the seeds and fruit are considered most so.<sup>2</sup> Its effects on man and other animals are almost, if not quite the same as those of belladonna, and its active principle, *daturia*, is considered identical with *atropia*.<sup>3</sup>

Its poisonous properties are not destroyed by heat, as numerous deaths from smoking the dried leaves testify.<sup>4</sup>

Symptoms of poisoning have followed the application of the extract to a blistered surface, bruising the leaves in a mortar, and even breathing the vapor of the full-blown flowers.<sup>2</sup>

The following cases of stramonium poisoning occurred in the neighborhood of the Federal Street "Common" where the plant abounds:—

On the evening of September 16th a man reported that his son, three years old, had cholera infantum. He stated that the child had gone to sleep as usual about six p. m., after playing out of doors all the afternoon; that he had awaked, kicking and screaming, about eight p. m., and that the face and body were scarlet.

It was found about 8.30 p. m. that there had been neither vomiting nor purging, and that the scarlet coloration remained only on the buttocks and thighs. The child was lying on the lap, kicking and throwing its arms about in every direction. Occasionally he would be convulsed, the eyes rolling upward beneath the upper lid, and he would be motionless a moment. The face wore a wild expression, the pupils were very widely dilated, and around the mouth the skin was white and pinched. Every few minutes he would suddenly grasp or pick at something which he seemed to see near him, and then immediately clutch at his mother's dress and bury his face as if frightened. Whenever asked a question he would attempt to speak, but would make only an unintelligible sound. The pulse was 160 and feeble, the respiration 64 per minute.

Because of suspected poisoning, large draughts of mustard and water were given, which brought up a considerable number of the half-masticated seeds and pieces of the seed covers of the thorn apple. A full dose of castor oil was given and treatment by opium begun. Ten drops of the deodorized tincture were given, and at the end of each quarter hour about three drops more, until thirty drops had been taken.

By this time the child was worse rather than better, and death seemed imminent from spasm of the glottis which had begun during treatment. Fearing to waste any more time with the *laudanum*, I went home for a hypodermic syringe, and on my return the parents asked that Dr. O'Leary might be called and he was accordingly sent for. The little patient seeming more comfortable treatment was suspended till Dr. O'Leary arrived, about eleven p. m. A twentieth of a grain of morphia was then injected beneath the skin, and at Dr.

O'Leary's suggestion a large soap and water enema was given, which, however, failed to come away.

The effect of the morphia was soon seen in the easier and slower breathing, and at 11.30 p. m. the child was asleep, breathing thirty-two times a minute. Soon after twelve p. m. a small movement of the bowels took place, and at this time the child seemed quite rational. He was left at one a. m. sleeping quietly. Respiration 21; pulse 130.

At the morning visit he was out at play. There were bronchial rales throughout the chest, and the pupils were still dilated. No other abnormal signs were noticed.

About ten p. m., during the course of the last case, a sister of the little boy, four years old, woke up and vomited. The face and body were reddened, and the pupils dilated. An emetic brought up quite a number of the seeds, but they had not been chewed. A few drops of the deodorized tincture of opium quieted her, and she went to sleep.

On the following evening I was called to see a boy, one and a half years old, who had had a convulsion. The scarlet efflorescence covered only the buttocks and thighs; the pupils were dilated, and there was considerable restlessness. An emetic brought up only a small piece of the green rind no larger than the thumb-nail. No seeds were found in the vomitus. He was given some castor oil and a moderate dose of opium.

Poisoning by stramonium may, I think, be properly divided into two stages. The first characterized by delirium, the second by coma, and between the two comes an intermediate stage, in which the patient may be aroused from a comatose condition and is then delirious. When the absorption of the poison is slow, the same symptoms which follow the administration of a medicinal dose, namely, slight dilatation of the pupil, thirst and dryness of the throat, precede the stage of delirium. The absorption may be so rapid, however, that the premonitory signs are entirely wanting and the first stage, even shortened to a few minutes. On the other hand, when treatment is begun early, or the amount of poison absorbed is not excessive, the patient may recover at the end of the stage of delirium without becoming comatose.

Among the first and most constant symptoms is dilatation of the pupils. This has been proved to be a local action,—a paralysis of the peripheral ends of the oculo-motor nerve and a stimulation of the sympathetic. One case is reported in which the pupils were found contracted.<sup>5</sup> A man took a drachm and a half of the tincture of stramonium before retiring. He was found in the morning unconscious, with the skin cold and clammy, hands and feet livid, the former much bruised, the pulse absent at the wrist, and the pupils so contracted as to be scarcely discernable. They began to dilate four and a half hours after. He was not able to give the circumstances of the poisoning until the fourth day.

It seems very probable that in this case the contracted pupils were not a direct result of the presence of stramonium. It is possible that enough of the drug had been eliminated during the night, so that a more powerful influence (perhaps the asphyxia from his long unconsciousness and the dyspnoea which is noted as present, or, more probably, uræmia from congestion of the

kidneys) was exerted in an opposite direction. The fact that the pupils began to dilate four and a half hours after treatment began tends to strengthen this view.

The scarlatinoid eruption generally present in stramonium poisoning was also absent in this case. It may have been absent from the first or have disappeared before the man was discovered. Its absence is noted in the cases of seven boys, inmates of a charitable institution, each of whom had eaten about ten of the nearly ripe seeds.<sup>1</sup> This eruption is usually one of the early symptoms, and tends to disappear, as in my case, some time before the other effects of the poison pass away. It resembles very closely the eruption of scarlatina, but lacks its punctate appearance. It is said that a crop of minute vesicles may follow the eruption,<sup>2</sup> or that the eruption may resemble erysipelas at first, and afterward measles.<sup>3</sup>

The pulse is usually rapid and weak, but is said to be strengthened and the number diminished at first, that is, before a large amount of the poison is absorbed. The primary slowing of the pulse may be explained by a stimulation of the inhibitory centres in the medulla, and the quickening which follows this by a paralysis of the vagus and consequent absence of the power to transmit the impulse. This does not explain, however, the infrequency of the pulse occasionally found among the reported cases.<sup>4</sup>

The respirations are almost always very greatly increased in frequency, due, it is thought, to stimulation of the respiratory centres in the medulla. In one set of cases, however, the respirations were less frequent than normally.<sup>5</sup> Croupy symptoms are quite commonly met with. They may be due to a swollen, turgid condition of the rima glottidis or to laryngeal spasm.

Vomiting and purging are not usually present in stramonium poisoning, though the text-books give these a place among the symptoms. Their occurrence seems to depend in a great measure on the rapidity with which the poison is absorbed. A large dose apparently paralyzes, and a small dose stimulates, the smooth muscular fibres. This is very well shown by the first two cases in this paper. The little boy had chewed the seeds and vomiting did not occur spontaneously and was not easily brought on by emetics. The paralysis of the rectal end of the intestinal tract was more marked. A soap and water enema of more than a pint, and containing also some salt, was retained until absorbed. On the other hand, in the sister, vomiting came on late in the evening, and the seeds found in the vomitus were not chewed. Vomiting<sup>6</sup> and diarrhoea<sup>7</sup> do occasionally occur. The action of stramonium in small doses as an aid to cathartics is well known clinically.

It is said that during the first stage the temperature is considerably raised. In the only case in which I find a record made it reached 104° F.<sup>8</sup> Loss of power in directing the limbs, together with choreic movements is almost universally present in the first stage.

Inability to talk, even when conscious, is generally

present. It is probably due to a loss of coördinating power in the muscles employed in speaking. It will be remembered that, in my case, active endeavors were made to answer questions without success, though the boy seemed to hear and understand what was said to him.

Occasionally convulsions occur in the early stages, probably from irritation of the spinal centres.

The delirium in stramonium poisoning is of a most peculiar kind. It is restless, talkative, and occasionally very violent. There are strange hallucinations and visions, and the patient seems to be unconscious of all that is going on around him. It is said that distant objects appear near and near ones magnified, which may explain some of the curious symptoms. In one case a man walked up and down stairs continually during a whole night. In another there was excessive laughter with other symptoms of mild intoxication by alcohol. Sometimes the patient will appear lost in a reverie, which will be broken by sudden cries and spasmodic motions. There is said to be a tendency to go about naked, and such was noticed in the well-known cases whose occurrence gave the plant its common name of "Jamestown weed."

Pain in the stomach and bowels,<sup>9</sup> and tympanites, have been noticed among the symptoms.

There is no tendency to sleep at any time. Insomnia and even delirium tremens are more likely to occur.

Paralysis is apt to follow convulsions, especially if the dose has been large, and quickly thrown into the system. It is thought to be due to the action of the drug on the peripheral nerves. The same stimulation of the spinal centres is exerted, but the motor nerves are not able to exercise their function.

The stage of delirium is generally followed by coma, broken, only at first, by moments of delirium. The pulse continues rapid and with decreasing strength, the respirations become slow, irregular, and very often stertorous; the temperature is lowered; the face and extremities become livid from non-aeration of the blood; there is often complete suppression of urine, and the patient dies from asphyxia, uræmia, or syncope.

In fatal cases death takes place within from six to twenty-four hours after symptoms of poisoning first manifest themselves, though in one case,<sup>10</sup> that of a feeble woman of sixty, death occurred on the fourth day after the patient was apparently convalescent. Death may occur after all the solid portions of the plant have been expelled by emetics and purgatives, as in the case of a little girl, two years old, who had eaten a hundred seeds. Twenty were vomited, and eighty came away through the bowels. A sufficient amount of the poisonous principle was absorbed during their passage.<sup>11</sup>

In the non-fatal cases recovery is usually complete by the third or fourth day, the dilatation of the pupils being the last symptom to disappear. Occasionally there are sequela, however. In one case in which a decoction of the leaves was drunk, gastric irritation remained a month.<sup>12</sup> In another, after treatment by emetics, cathartics, and opium, a most curious after-effect was stammering, which the child was free from before the poisoning.<sup>13</sup>

stramonium are by no means characteristic, and depend to a great extent, I judge, on the symptoms preceding death. In one case the larynx and œsophagus were slightly reddened, the rima glottidis thickened and turgid, and the blood semi-fluid.<sup>1</sup> In this case, as in mine, there were croupy symptoms, but in the latter it was thought that the dyspnea was due to spasm, rather than to any change in the larynx itself. In another case there were found, after death, a high degree of congestion of the brain and its membranes, together with an effusion of bloody serum into the ventricles. The mucous membrane of the stomach was highly congested, and there were two points of extravasation.<sup>2</sup> Another case showed the lungs oedematous, and the right heart full of blood.

Symptoms of an over-dose of stramonium usually manifest themselves in an hour or two after the ingestion, though of course the length of time which the stramonium may lie in the stomach depends, to a great extent, on the condition of that organ, as well as on the form in which the stramonium is administered. They may be delayed for a considerable time, as in my second case, or, on the other hand, after a fluid preparation, for example, the decoction, has been taken, delirium, staggering, and even unconsciousness may come on in a few minutes.

The diagnosis of poisoning by a mydriatic is not usually difficult, though to distinguish which drug of this class has been taken is often impossible. The symptoms of scarlet fever resemble poisoning by stramonium most closely, especially in children.<sup>3</sup> There is a sudden invasion, a scarlet eruption, a reddened throat, and a hot, dry skin, but the peculiar restlessness and odd contortions, together with a wild expression, dilated pupils, and more feeble pulse, make it impossible in most cases to mistake the two.

I have heard of several deaths from "convulsions," where no physician was called, and in three of these the symptoms, as described, might well belong to stramonium poisoning. These cases occurred in the same neighborhood to which those reported in this paper belong.

If an emetic is given, and portions of the plant are found in the vomitus, the diagnosis is of course made.

In doubtful cases, if a sufficient amount of urine can be obtained, a portion may be injected beneath the skin of the ear or dropped into its eye, and the dilated pupil will show the nature of the poison.

The treatment of stramonium poisoning begins, of course, by emptying the stomach. Ordinary emetics often act slowly or not at all, and the use of the stomach-pump becomes necessary. It is best, also, to give a cathartic, to be followed by a stimulating enema, for so much time often elapses between the ingestion of the poison and the appearance of the symptoms that a considerable portion of the drug may have passed the pylorus.

As an antidote before absorption has taken place, animal charcoal is mentioned for stramonium as well as for aconite,<sup>4</sup> and tannin forms with the active principle a difficultly soluble compound as with the other alkaloids.

During the first stage cool baths have been used to reduce the temperature. Antimony as a depressant and numerous other drugs have been given with good

results, but in opium (or morphia) we have the nearest to a physiological antidote. Its action is most marked if given during the stage of delirium, but its antagonistic effects may be noticed even after the patient is comatose. The hypodermic injection of morphia is preferred to any other method of administration, as its effects are more rapid, and more under control. It requires care in using, and the dose to be given depends on the gravity of the symptoms. The pupil is considered by some to be a guide in giving opium, though by others this is denied. From a physiological point of view it is not a safe guide, because stramonium dilates the pupil by a local action, while opium contracts it by influencing the nerve centres.

After the patient has become comatose treatment by opium does not seem to be so rational. It is said to be most beneficial when a large amount of water can be thrown into the system at the same time,<sup>5</sup> and when it is remembered that there is often suppression of urine, and that by means of the urine nearly all the poisonous principle of the stramonium must be eliminated, such a result will be expected.

It has been noticed, in a case of atropia poisoning, that the stertor increased after each injection of morphia, and it was discontinued. In the comatose stage the danger is failure either of the heart or respiratory muscles, and opium in large doses acts in the same direction. It is not a perfect physiological antidote. One case is reported, however, in which an improvement in the pulse took place after each injection of morphia, though in the end the patient died.<sup>6</sup>

Hot and cold douches, faradization, and the administration of alcoholic stimulants have given good results. Small doses of camphor in the form of an enema have been considerably praised,<sup>7</sup> although I find no mention of the use of digitalis in stramonium poisoning; its physiological action suggests its use as a stimulant to the circulation.

Artificial respiration is a very important aid in the later stages when the respirations become infrequent, and the patient is becoming asphyxiated.

In a recent journal<sup>8</sup> chloroform is spoken of as a physiological antidote for stramonium, and a case is given in which an exceedingly good result was obtained by its inhalation.

I cannot forbear, in closing, from suggesting that the Society call the attention of the proper authorities to the dangers to which children are liable from the presence of this poisonous weed within the city. The experiment of exterminating it might be begun on the Federal Street Common, for instance, which is the play-ground, not only for the children belonging to the school recently established there, but for a large Irish neighborhood, as well. Though some may think it an exaggeration, the plants almost out-number the children.

— Sir James Paget, in an article in the *Nineteenth Century*, thus illustrates the condition of English anti-vivisection law: "I may pay a rat-catcher to destroy all the rats in my house with any poison he pleases, but I may not myself, unless with a license from the Home Secretary, poison them with snake-poison."

## RECENT PROGRESS IN MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M. D.  
TOXICOLOGY.

## SULPHURETTED HYDROGEN.

Much of the sulphide of iron sold to chemists for the generation of sulphuretted hydrogen rests almost completely the action of dilute acids. P. Casanajor<sup>1</sup> states that an abundant supply of the gas can be obtained from such samples, by proceeding as follows. Enough mercury is put in a bottle to cover the bottom entirely. Over this, dilute sulphuric acid is poured, and some pieces of zinc are thrown in, which immediately sink in the mercury, forming a zinc amalgam with a great excess of mercury. No action takes place between the zinc and the acid. If now a few pieces of sulphide of iron are thrown into the bottle, they will sink to the mercury, and a copious discharge of sulphuretted hydrogen will take place from the surface of the sulphide of iron. This production will continue with remarkable regularity until either the zinc, the sulphide of iron, or the sulphuric acid is exhausted. The mercury only intervenes indirectly in the reaction, and does not require to be renewed.

## CARBONIC OXIDE.

M. Gruber<sup>2</sup> has made experiments with a mixture of air and 0.02 to 0.5 per cent. carbonic oxide, on rabbits, fowls, and white mice, the time of exposure varying from ten hours to three and one half days. Poisonous or injurious effects were noticed with very small quantities of the gaseous mixture. The limit of poisoning depends on the concentration of the gas, and not on the time of exposure. Carbonic oxide is inactive when present in the air to the extent of only 0.02 to 0.05 per cent. Air contaminated with 0.25 per cent. of the gas is highly poisonous. The author states that coal gas in dwelling-rooms can always be recognized by its smell, before it is possible to identify the carbonic oxide. He also says that in no case could carbonic oxide be found when rooms were heated with hot air or iron stoves.

Edwin Kreis<sup>3</sup> concludes from numerous experiments that, in cases of poisoning by carbonic oxide, only a very small part of the carbonic oxide is eliminated as such in the breath; and that the elimination of this small quantity is explained by the fact that carbonic-oxide-haemoglobin is not a perfectly stable combination, but possesses a certain tension by virtue of which it gives up a part of its carbonic oxide to any space free from the gas. The greater part of the gas is destroyed, and as he has found that animals poisoned with carbonic oxide eliminate more carbonic acid gas than those not poisoned, he concludes that the greater part of the carbonic oxide is changed to carbonic acid. Whether this change is a direct one or whether some other oxidation product is first formed is not determined. These conclusions of Kreis differ from those of Gréhant, who believes that carbonic oxide is for the most part eliminated as such in the breath.

## MORPHIA AND CODEIA.

E. Grimaux<sup>4</sup> has established a close relationship between these two constituents of opium by the conver-

sion of morphia into codeia. If a solution of morphia in alcoholic potassa or soda is gently warmed with an excess of methyl iodide, there is formed the iodo-methylate of codeia similar in all respects to the compound obtained by treating codeia with methyl iodide. If a very small quantity only of methyl iodide is employed, a small amount of free codeia is formed, and the artificial codeia possesses all the characteristics of the alkaloid extracted from opium. A careful study of the properties of morphia leads to the conclusion that it is analogous to the phenols and that codeia, which differs from it in composition by  $\text{CH}_2$ , is its methyl ether.

## STRYCHNIA.

F. J. Sommenschein<sup>5</sup> announced a few years since that when brucia is gently warmed with four or five times its weight of dilute nitric acid, strychnia, among other products, is formed. A. Claus and R. Röhre<sup>6</sup> and W. A. Stenstone<sup>7</sup> have carefully investigated this subject, and maintain strongly that when *perfectly pure* brucia (that is, brucia free from strychnia) is treated with dilute nitric acid, not even a trace of strychnia is formed.

## STABILITY OF CALOMEL.

P. Høglan<sup>8</sup> has made a series of experiments to discover the cause of the differences of opinion which exist concerning the conversion of calomel to corrosive sublimate by the alkaline chlorides and citric acid. The author's experiments show that calomel is slowly converted to corrosive sublimate by water at the temperature of the body; that common salt, sal-ammoniac, citric acid, and hydrochloric acid greatly promote this conversion, and hence are more or less dangerous when present in the system with calomel; that at the temperature of the body calomel is an unstable compound. Høglan found that when calomel and sugar were triturated together, no corrosive sublimate could be detected even after a fortnight; that when calomel was treated in the same way with magnesia, carbonate of magnesia, or bicarbonate of sodium, the mixture yielded evidence of corrosive sublimate at the end of twenty-four hours. The author concludes that the discrepancies in regard to the stability of calomel are in part accounted for by taking into consideration the temperature at which the experiments have been conducted.

## POISONING BY INHALING CHROME YELLOW.

Dr. Robert C. Smith<sup>9</sup> reports two cases of this form of poisoning. The patients were employed in weaving yarn colored with chromate of lead, which was only loosely applied, so that it was readily given up from the yarn in the process of weaving. The description of the symptoms in these cases is very brief, and apparently incomplete. The author, however, calls particular attention to the fact that the skin and conjunctivæ were yellow, so that the patients seemed at first sight to be suffering from an acute attack of jaundice. The urine, however, contained no bile pigment. The yellow tint of the skin was the first symptom to disappear, the blue line on the gums the last. In one case the urine contained chromium, while lead could not be detected. The author concludes that after absorption the chromate of lead is decomposed, and that

<sup>4</sup> Comptes Rendus, xxi., pages 1140 and 1225.

the chronic acid stains the liquor sanguinis and skin for a time, finally leaving the body by the liver and kidneys, while the lead is fixed in the tissues.

#### ELIMINATION OF MERCURY BY THE KIDNEYS.

Oberländer<sup>1</sup> concludes from a considerable number of analyses that the normal elimination of mercury through the urine may be determined as long as one hundred and ninety days after the cessation of specific treatment. Its course is irregular, and is marked by remissions and even by temporary pauses of variable duration. (Mercury has been detected in the liver when none had been taken for a year before death. REP.)

#### POISONING BY CHLORATE OF POTASSIUM.

Chlorate of potassium in over-doses has, during the past few years, been the cause of several fatal cases of poisoning, especially in children. M. Ludwig,<sup>2</sup> in a case of this kind, examined the blood, the contents of the stomach, and the urine. The latter was turbid, the reaction acid. It contained an abundant sediment, composed of blood globules in small number, and large granular casts. He could not detect the salt either in the blood, urine, or contents of the stomach. It seems to be reduced in some unknown way in the body either in whole or in great part. According to the author, chlorate of potassium seems to act in a manner similar to arsenic and phosphorus. The blood reduces it to chloride of potassium, and the blood globules are destroyed, while the feebly acid urine decomposes it, in the kidneys, into a base and chloric acid, the latter compound having a marked effect on the kidneys.

#### URINARY CHEMISTRY.

##### BILIARY COLORING MATTERS.

Gerhardt<sup>3</sup> describes the following reactions. Mix the chloroform extract from an icteric urine with impure (that is, oxidized) oil of turpentine and a small amount of a dilute solution of potassic hydrate. The solution assumes a green color. The same reaction occurs upon the addition of potassic hydrate and a small amount of a very dilute solution of iodine in iodide of potassium.

Urine containing urobilin shows a very characteristic reaction with iodine and potassic hydrate. Add to the chloroform extract iodine, and then neutralize the latter by shaking with dilute potassic hydrate. The potassic hydrate solution assumes a yellow or brownish-yellow color with a beautiful green fluorescence. This reaction can also be obtained directly from any urine containing urobilin, in which case chlorine water can be substituted for iodine.

##### BILIARY ACIDS.

Drechsel<sup>4</sup> modifies Pettenkofer's test for the biliary acids as follows: The solution containing the biliary salts is concentrated to a syrupy consistence, and to it is added concentrated syrupy phosphoric acid; a solution of sugar is then added, and the mixture is heated by holding the test tube containing it in some boiling water. If any trace of the biliary acids is present the mixture will assume a red to purple-violet color

after heating for a short time, even when the sugar is in considerable excess, since sugar is much less easily acted upon by phosphoric acid than by sulphuric acid

#### URIC ACID.

E. Ludwig<sup>5</sup> recommends the following method for the quantitative estimation of uric acid. To the urine is added a mixture of ammoniacal silver solution and magnesium fluid. The precipitate containing all the uric acid and phosphoric acid is transferred to a filter paper, washed well with water containing ammonia, decomposed by the aid of heat with a dilute solution of potassic sulphide, and filtered. Urate of potassium is formed which goes into solution. The filtrate and washings are acidified with dilute hydrochloric acid, and evaporated on a water bath to a small volume. The uric acid which separates upon cooling is collected upon a filter, washed with water, dried at 110° C., and freed from sulphur by washing with bisulphide of carbon, and finally with ether.

#### REAGENTS FOR ALBUMEN IN THE URINE.

C. Hindenlang<sup>6</sup> has compared metaphosphoric acid with other reagents for the detection of albumen, and has obtained remarkably good results. He finds that albumen is the only constituent, normal or abnormal, of the urine with which the acid produces any turbidity. The test is performed as follows: A fragment of the acid is shaken with two or three cubic centimetres of cold water till a sufficiently strong solution is obtained, and this is added to the urine previously filtered. The least trace of albumen is indicated, without warming the mixture, by an opalescence or distinct turbidity.

A. Raabe<sup>7</sup> recommends the use of trichloroacetic acid as a reagent for albumen. A small crystal of the acid is dropped into a test tube containing a few cubic centimetres of filtered urine. The mixture is not to be shaken. There is thus formed in the bottom of the tube a concentrated solution of the acid. If albumen is present there will be formed, after some minutes, a zone of coagulated albumen, which does not disappear upon warming, thus differing from urates. This reagent causes no turbidity in normal urine, but causes a deposit of uric acid in urines containing a large amount of urates. Previous dilution of the urine will often prevent the deposition of uric acid. By this reagent Raabe could recognize 0.0295 grammes of albumen in 250 c. c. The reagent is six times more sensitive than metaphosphoric acid, and two times more sensitive than nitric acid.

#### ACID FERMENTATION OF URINE.

According to Scherer an acid fermentation, in which by the action of the mucus the urinary pigments are decomposed, with the formation of lactic and acetic acids, precedes the well-known alkaline fermentation of the urine. F. Röhmam<sup>8</sup> publishes the results of his investigations upon this question. He has determined by titration the acidity of a large number of normal and abnormal urines (fresh urines previous to the occurrence of the alkaline reaction) in order to determine whether there is an increase or diminution of acidity, and has made numerous determinations of the ammo-

<sup>1</sup> The Dublin Journal of Medical Science, 1881, page 528, from Rep. de Pharm., August, 1881.

<sup>6</sup> Archiv der Pharmacie, July, 1881, page 56, from Berlin. klin. Woch., 1881, No. 15.

<sup>7</sup> Berichte der deutschen Chemischen Gesellschaft, xiv., page 2312, from Pharm. Zeitschr. f. Russland, 1881, page 445.

<sup>8</sup> Chemisches Centralblatt, 1881, page 378.

nia. His investigations show that an acid fermentation, as understood by Scherer, does not exist. Only exceptionally did an acid urine show any increase of acidity, and in these cases the increase was an accidental occurrence due to the presence in the urine of substances prone to ferment, and which by fermentation furnished an acid; such as alcohol or sugar. Ordinarily the acidity, as well as the amount of ammonia which was present when the urine was passed, remained unchanged for a shorter or longer time; then the acidity diminished, the ammonia increasing, till the reaction of the urine became alkaline. Still while the urine reacted acid (the same was true also in case of those urines the reaction of which was alkaline from the first) a urine which when passed was clear became cloudy, and at the same time the reaction for nitrous acid was obtained. The nitrous acid may exist in small proportion in the fresh urine, or may be formed in part from the nitrates in the urine, or possibly, in part, in alkaline urines, from the oxidation of ammonia. The nitrous acid gradually diminishes, and disappears after a while. It may be present, however, when the urine has an alkaline reaction.

#### DIABETES MELLITUS AND ALBUMINURIA.

According to Ferrieh,<sup>1</sup> in true diabetes albuminuria is not frequent, nephritis is rare, and occurs only in certain conditions. Out of 316 cases of diabetes mellitus which Ferrieh partly observed for ten, twelve, and even fifteen or sixteen years, there were only sixteen cases of nephritis. Cases in which small quantities of albumen were occasionally found in the urine were never pure and simple cases, since it could be proved in most of them that other processes were involved which of themselves could produce nephritis. Of sixteen cases there were only three in which no co-operating cause could be suggested. The author concludes that the general belief that the increased action of the kidneys in diabetes mellitus leads to albuminuria and nephritis is erroneous. According to the author's post-mortem examinations, which comprise more than fifty cases, true nephritis is hardly ever met with in diabetes.

#### DIABETIC ACETONURIA.

Many investigations have been made for the purpose of determining, if possible, the nature of that constituent of the urine of patients suffering from the more intense forms of diabetes mellitus which gives the red coloration with ferric chloride. The reaction has been attributed by many chemists to the presence of ethyl-aceto-acetate, which would yield by its decomposition an equal number of molecules of acetone and alcohol. Owing to the volatility of the acetone the proportion of alcohol may even exceed that of the acetone. In all cases which have been examined, however, the reverse has been well marked. A. Deichmüller,<sup>2</sup> for example, failed to obtain alcohol from forty litres of a diabetic urine. He made a series of determinations of the acetone in the urine, and found it in quantity varying between .093 and .147 per cent. As the reaction with ferric chloride points to the presence of a compound allied to ethyl-aceto-acetate, and as no alcohol was separable from the distillate, the author concludes that the compound is not ethyl-aceto-acetate but free aceto-acetic acid. In this opinion he is confirmed

by B. Tollens.<sup>3</sup> The latter bases his opinion upon the experiments of Deichmüller, as well as upon the fact, which he himself observed, that when diabetic urine was shaken with ether only a slight trace of the ferric chloride reaction was obtained from the ether extract; when, however, he added to the urine one tenth of its volume of a one and one half per cent. aqueous solution of ethyl-aceto-acetate the latter was readily extracted by ether.

### Hospital Practice and Clinical Memoranda.

#### A CASE OF UNUSUAL TOLERANCE OF SULPHATE OF MORPHIA.\*

BY GEORGE A. BRUG, M. D., PROVIDENCE, R. I.

MONDAY, December 5th. I was called to see Mrs. G., aged forty-six years, I found my patient in a state of extreme collapse, with violent attempts at vomiting; radial pulse imperceptible; surface covered with cold perspiration; countenance expressive of extreme agony; tossing about in her bed and begging for death, or relief from her terrible suffering, which was referred principally to her stomach, with minor pains in all parts of her body.

I found upon inquiry that she had been addicted to the use of morphia, and had made the attempt to break off the habit, which had resulted in her present condition. She had used the drug almost continually for the past fourteen years, during which time she had entirely abstained from its use three times for periods of two to three months each, but has taken it without intermission during the past nine years. She first began using it for the relief of pain from rheumatism, beginning with one fourth grain and continued after her recovery, gradually increasing the daily amount to from fifteen to twenty grains. She would occasionally double this amount for a few days, when there was anything to trouble her mind, upon such days taking from thirty to forty grains, but would diminish the amount when her trials were passed.

For three weeks previous to December 5th she had had a great deal to worry about, and during this time she took regularly a *drachm* of sulphate of morphia daily, on several days *eighty* grains. The entire daily allowance was taken within two or three hours, or from

<sup>1</sup> The London Medical Record, August 15, 1881, page 312.

<sup>2</sup> Journal of the Chemical Society, London, 1881, page 1162, from Liebig's Annalen, cxix., page 22.

<sup>3</sup> Liebig's Annalen, cxix., page 30.

\* Read before the R. I. Medical Society, at the Quarterly Meeting, Thursday, December 15, 1881.

two to five o'clock in the afternoon, taking about fifteen grains at a dose. Before taking her morphine she was very uncomfortable and restless, after taking it quiet and easy, and would then engage in conversation or in reading. She could never sleep until ten or twelve hours after having taken the last dose, and then would not sleep more than two or three hours out of the twenty-four.

She eats very little, taking usually nothing but a small piece of toast and a little milk in the forenoon, after which she takes no food until the following day, when the above is repeated, yet she appears to be well nourished, her present weight being one hundred and seventy-five pounds.

As I stated before, prior to December 5th she had been taking a drachm or more daily, but had decided to stop using the drug, and the day before had taken but half her usual quantity, that is, thirty grains, and the Monday following had taken none previous to the outset of the symptoms described at the time I saw her. Her husband then compelled her to take some, but the stomach refused to retain it.

Upon my arrival I at once injected hypodermically one grain of sulphate of morphia, after fifteen minutes two grains, followed by an additional two grains, finally one grain more, making a total of six grains hypodermically in less than an hour, at the end of which time she was not comfortable, but so far relieved that her suffering was endurable. She begged me to add one more hypodermic of four grains, which she thought would make her easy, but I refused since I considered her symptoms so far relieved that she was out of danger, and I did not dare use more. After I left her she used three suppositories of five grains each, and shortly after fifteen grains by the stomach.

The following day she had completely recovered from her collapse and was in her usual health. She has since been breaking off more gradually, determined, however, to do away with the use of morphia altogether.

## Reports of Societies.

### QUARTERLY MEETING OF THE RHODE ISLAND MEDICAL SOCIETY.

G. D. HERSEY OF PROVIDENCE, SECRETARY.

THE customary quarterly meeting of the Rhode Island Medical Society was held in Providence, December 15, 1881.

DR. C. V. CHAPIN read a paper on

#### THE OCCURRENCE OF INTERMITTENT FEVER IN PROVIDENCE AND VICINITY DURING THE PAST SUMMER.

The essay of Dr. Oliver Wendell Holmes, published in 1836, was quoted, showing that intermittent fever existed in New England to a moderate extent from its settlement till the early part of the present century, and that at the time of the Revolution it occurred in Providence, Cranston, and South Kingstown, while other parts of the State escaped. Dr. Usher Parsons, in a letter to Dr. Holmes, states that he had known of chills and fever many years before in the northern section of Providence in the neighborhood of a dam which had been thrown across the Moshassuck River. But for the past fifty years Rhode Island, with the most of New England, has had complete immunity from ma-

larial affections. In the summer of 1880 a marked epidemic of intermittent fever appeared at Nayatt, ten miles down the bay. While it was altogether the most severe at that place many other localities were also affected, and a few cases were observed in Providence in the vicinity of Mashapaug pond. During the summer just past a very large number of cases occurred within the city limits, and the effort to collect them suggested this paper. Inquiries were made of one hundred and fifteen practitioners, replies being received from seventy-four. Of these, thirty-one reported cases and forty-three reported having none. Four physicians practicing in one locality had a considerable number each, while of the remainder scarcely any one had more than half a dozen. In all, three hundred cases were reported. One hundred and eighty-seven, or 62 per cent., were within half a mile of Mashapaug pond; twenty-six, or 8 per cent., were near the Oriental mill; eight, or 2½ per cent., were near Red Bridge. This leaves seventy-nine cases scattered over the city where no apparent cause could be found. The population of the Mashapaug district is 2500, and the cases of malaria reported numbered one to each fourteen of the population. The seventy-nine cases in the rest of the city with a population of 100,000 gave one in 1250. There was not a single death reported from malarial disease. This record is unavoidably imperfect, as many people bought medicine of their apothecary or used prescriptions given by physicians to other sufferers.

Though we do not know the exact nature of the cause of intermittent fever, we do know many of the conditions under which it is active. Some of these conditions the experience of two summers has illustrated. The malarial poison is not developed until the minimum temperature rises above 57° F., so that it rarely appears in this latitude till summer is somewhat advanced. It may then increase until the thermometer marks 82° F., which effectually checks its production. But many cases which contract the disease in the fall do not have any manifestations of it till well into the winter.

Again, the most important conditions for the development of malaria are humidity and the presence of dead vegetation. The outbreak at Nayatt in 1880 was in a region of marshy land with shallow pools of stagnant water abounding in decaying vegetable matter. The same condition is true in a general way of the lower portions of the Pawtuxet and Woonasquatucket valleys. The flooding of the meadows at Nayatt, near which most of the cases of fever occurred, has resulted in a marked diminution in the number of cases in that immediate neighborhood. Thus demonstrating in the most practical way the relation between malaria and wet lands. If the swampy ground around Mashapaug and Spectacle ponds and near the Oriental mill could be drained, or else kept deeply covered with water, there would probably be less intermittent fever next summer in those localities.

DR. BATCHELDER, of Arlington-in-Cranston, reported one hundred and seventy-five cases of malarial disease observed the past season in the territory adjoining the "Mashapaug district."

DR. HUNT, of East Providence, had recently seen cases of intermittent fever where the ground was high and dry, but where the sanitary surroundings of the locality were very imperfect. Typhoid fever rather than intermittent would be looked for under similar conditions.

DR. GARVIN, of Lonsdale, had observed malarial disease appearing along a line of excavations made in laying water pipes from Pawtucket to Lonsdale.

DR. REMICK called attention to the present infrequency of typhoid fever in Providence, especially in localities where intermittent abounds.

#### MALARIAL KERATITIS.

DR. H. G. MILLER mentioned malarial keratitis, an obstinate form of ulceration of the cornea, as one of the sequelae of malarial fever. He had recently seen four cases. Of these, one originated at Nayatt and one at Lonsdale in Rhode Island, one at Taunton, Mass., and one at the West. The trouble appears during or after convalescence from the febrile attack, and varies in extent and severity from a simple loss of epithelium to a deep and widespread ulceration. The most striking symptom is anesthesia of the cornea. Notwithstanding the severe pain which may be present, both in the eye and around the orbit, the cornea is quite insensible to the touch as compared with that of the healthy eye. But the tension of the globe is not increased as in glaucoma. In addition to the antiperiodic and general tonic treatment indicated the best local remedies have appeared to be atropine in solution dropped into the eye in the usual way, and finely powdered iodoform dusted in with a camel's hair brush, each two or three times a day. Solutions of eserine and pilocarpine appeared to be irritating. The speaker thought he might formerly have seen cases of obstinate keratitis arising from this cause without having recognized its source; but after having his attention called by Prof. Henry D. Noyes to their occurrence near New York, where malarial diseases are much more common, he had been on the watch for them since the great increase of fever and ague here.

DR. WILLIAM SHAW BOWEN reported

#### A CASE OF LARYNGEAL PARALYSIS SUPPOSED TO BE DUE TO MALARIAL POISONING.

A male, aged 37, otherwise in good health, a non-user of alcohol or tobacco, and with no history of syphilis, came under observation with practically complete aphonia. He had been for several months in the West and while there had a severe attack of malarial fever of the remittent type. This was followed by quotidian ague which continued up to a fortnight previous to coming for consultation. Large quantities of quinine and salicylic acid had been used. The loss of voice commenced suddenly, during a chill, about four weeks previous. Examination revealed healthy fauces, nasal passages, and pharynx. The mirror showed that on attempting phonation the cords did not approach. There was slightly increased color of the cords and ventricular bands, but no other morbid process existed. The diagnosis was bilateral paralysis of the crico-arytenoidei laterales and the arytenoideus. This condition is almost invariably due to functional causes, especially impoverishment of the blood, amenorrhœa, and sometimes hysteria. It usually yields readily to faradization locally applied. In this instance the current proved of no value and two grains of quinine every two hours were ordered. Stimulating inhalations were advised, but only irregularly employed. In ten days guttural sounds could be made, and in another fortnight the voice had returned to its normal condition. The quinine treatment was continued four weeks in all. Dr. Bowen had seen no recorded case of

such influence of malaria on the vocal organs, and presented this seeming instance of implication of the adductor muscles of the larynx as a possible means of bringing to light other cases of a similar nature.

#### STRAMONIUM POISONING.

DR. H. TERRY read a paper on stramonium poisoning, relating three cases recently under treatment.<sup>1</sup>

DR. CHAPIN recited the history of three patients who were poisoned by accidentally drinking an infusion of stramonium leaves. He noticed the same nervous symptoms described by Dr. Terry. One of his cases fell into collapse but was revived with stimulants.

DR. F. H. PECKHAM, JR., had also observed three cases of stramonium poisoning. He noticed particularly the eruption simulating that of scarlet fever.

DR. G. A. BRUG read notes of a case of

#### UNUSUAL TOLERANCE OF MORPHINE.<sup>2</sup>

A woman, aged forty-six, had used morphine without intermission for nine years; 10-20 grains being the average daily allowance, occasionally doubling the amount when worried. Recently she had increased the daily supply to sixty and even eighty grains.

#### ABSCESS OF THE LIVER.

DR. HUNT presented a paper on abscess of the liver, founded on a recent case of typhoid fever with hepatic abscess which terminated fatally on the twenty-eighth day. At the post-mortem examination the liver was found firmly adherent to neighboring organs. One large abscess contained eight ounces of pus, and there were numerous smaller abscesses.

DR. LEONARD reported a case of abscess communicating with the gall-bladder in a man aged eighty. The abscess seemed to be quite superficial, was aspirated three times in three weeks, and eventually discharged fifteen gall stones. The patient recovered with a biliary fistula through which twenty-five small calculi have passed.

#### TREATMENT OF PUERPERAL CONVULSIONS.

DR. E. T. CASWELL read a paper on the treatment of puerperal convulsions occurring at the time of labor. The two prominent indications are control of the spasms and a rapid termination of the labor. Morphine in large doses as advocated by Dr. C. C. P. Clark, of Oswego, in the *American Journal of Obstetrics* for July, 1880, was recommended to check the convulsions; one grain being the maximum single dose. In the writer's experience Molesworth's dilators had proved very serviceable in securing a rapid dilatation of the os.

#### DELEGATES AND FELLOWS.

Delegates to State Medical Societies were appointed as follows:—

To Maine, A. A. Mann of Central Falls, and W. H. Traver of Providence; New Hampshire, S. Hunt of East Providence and W. E. Anthony of Providence; Vermont, Lloyd Morton of Pawtucket and E. P. Clark of Hope Valley; Massachusetts, Ariel Ballou of Woonsocket and W. O. Brown of Providence; Connecticut, A. G. Browning and G. D. Hersey of Providence; New York, L. F. C. Garvin of Lonsdale and R. F. Noyes of Providence; New Jersey, C. H. Fisher of North Seituete and E. B. Eddy of Johnston.

<sup>1</sup> See page 123 of this number of the JOURNAL.

<sup>2</sup> See page 128 of this number of the JOURNAL.

Drs. J. Howard Morgan of Westerly, Joseph E. V. Mathew of Central Falls, William J. McCaw of Providence, and Edwin A. Kemp of Lonsdale were elected Fellows.

#### NORFOLK DISTRICT MEDICAL SOCIETY.

WALTER CHANNING, M. D., SECRETARY.

A MEETING for scientific improvement was held at Rockland Hall, Roxbury, on Tuesday, November 29, 1881. Present twenty-one members. At 2.30 p. m., the vice-president, Dr. Dearing, called the Society to order and in the absence of the secretary, Dr. Walter Channing, Dr. G. D. Townshend was appointed secretary *pro tem*.

THE INTERNATIONAL MEDICAL CONGRESS, 1881, AND THE MEETING OF THE BRITISH MEDICAL ASSOCIATION; LISTERISM; VACCINATION; NEW INSTRUMENTS, ETC.

DR. HENRY A. MARTIN gave a brief account of some of his experiences while in attendance on the 1881 International Medical Congress, London; and at the meeting of the British Medical Association at Ryde, Isle of Wight. The speaker stated that he found his rubber bandage was approved and extensively used by the members of the Congress, especially in England.

The germ theory he thought met with a cool reception in the Medical Congress, and, in the speaker's own mind, in less than twenty-five years that now popular theory would be one of the exploded fallacies. We in this country have not a definite idea of the extreme precision of the Listerian method as practiced under Mr. Lister's immediate supervision. For instance: In a case of fracture of the patella, with an apparently most favorable result, Dr. Martin attempted to touch the part over the fracture, in order to ascertain the degree and character of the union of the fragments, when he was instantly warned off by Mr. Lister himself.

In a case of acute hydrocele, or orchitis, treated by puncturing, a huge mass of gauze, "protective" and general Listerian wrappings the size of one's head, was found at the foot of the bed when the patient was exposed by Mr. Lister, or his assistants, to the invited visitor's inspection. In England there is considerable diminution in confidence in the "spray," and in the extreme or routine "Lister-dressing" too, to a certain extent. Mr. Thomas Keith's statement at the Congress did much to strengthen many previous doubters of Mr. Lister's theories. Mr. Keith and several of his assistants or attendants in his hospital had suffered from albuminuria arising from carbolic acid poisoning. Mr. Keith went to the continent twice thinking himself incurably affected, but he recovered both times. Professor Lister was considerably disconcerted by Mr. Keith's statements.

Because the allotted time for speakers in the Congress was limited by rule to ten minutes, and Dr. Martin found the rule inflexible towards himself, although frequent exceptions towards some others were not wanting, he preferred to accept the opportunity offered, of twenty minutes, by the British Medical Association, at Ryde, Isle of Wight.

At the close of the Congress Dr. Martin was called upon to address that body; his remarks then are in-

cluded in the report of the transactions of the Congress. He was the guest of the Public Medicine Section of the British Medical Association. He could warmly add his testimony to that of many other witnesses in favor of this perfectly delightful watering place.

Dr. Martin had addressed this Public Medicine Section eight years previous and had then predicted the great importance of animal vaccination, which was not then appreciated. They have since pretty fully recognized the thoroughly established fact that humanized virus becomes extinct. It is quite characteristic of the traditional British conservatism, that the profession generally in Great Britain is waiting for a case of true English cow-pox, before it will countenance animal vaccination. No less characteristic is the British law that no new surgical operation can be performed without a "Board's" permission. Dr. Cameron, M. P., from Glasgow, is an advocate of animal vaccination. Dr. Wm. B. Carpenter, the celebrated physiologist, invited Dr. Martin to dine with him, and to meet several prominent gentlemen. The attentive host proved himself a delightful old gentleman.

Dr. Carpenter stated that he had received from his three books on physiology only about £100 in Great Britain, and £900, as a sort of conscience money, from America. Dr. Martin pronounced this fact a very marked instance of the absurdity of a man being deprived of the benefits of his ability as an author.

In his rambles the speaker saw "loads of things" but he brought home very few articles, among which, however, was one he could highly approve, a vaccine shield, of coarse wire work, with a covered rim, and two tapes attached to this rim, to fasten the shield on the arm, so as to protect the vaccine vesicle from being irritated by clothing, etc., which irritation produces most of the bad cases sometimes seen. Messrs. Leach and Greene of Boston had been given suggestions concerning such a shield.

Dr. Martin exhibited also a small specimen of a syphon arrangement of small rubber tubing and a central double metallic coil, for hot or cold applications to the parts requiring them; both applications are greatly intensified by this simple apparatus. There are various sizes and forms of this apparatus, adapted to different parts of the body.

A set of Mr. Spanton's corkscrew-like instruments, for use in his method of operating for the radical cure of inguinal hernia, were exhibited. These instruments span the inguinal canal from pillar to pillar, and from the external ring to the scrotal wound and retain a cylindrical plug of invaginated subcutaneous tissues, up into or against the internal ring, until adhesive inflammation results and fixes this plug and obliterates the canal. Spanton's results have been invariably beneficial — all but .05 per cent. had been curative, and this remaining .05 per cent. had been decidedly benefited. No grave inflammatory symptoms had occurred. The only danger is of wounding a branch of the internal epigastric artery.

A truss has been worn for a week or two after some of Spanton's operations, but it was not necessary to use one. Dr. Martin considers this operation "a most sensible one, and one possessing the advantage that it can be performed by ordinary human beings."

Dr. Martin spoke very favorably of his kind reception and recognition.

DR. DEARING spoke of several foreign medical men whom he met, and of some operations that he wit-

nessed while he was at the Congress. He mentioned also the existence of various opinions concerning the Listerian method of treating wounds.

DR. GEORGE E. MACUEN then read an account of

#### A JEWISH CIRCUMCISION,

of which the following is a summary:—

The ceremony or operation was performed upon an infant, born of Jewish parents, eight days old, and the fact that the said infant was born on a Saturday, or the Jewish Sabbath, was said to add additional lustre to the ceremony and confer great honor upon the infant.

A room was prepared by having a table near the window, water, sponge, towels, and lint, in about the same manner any physician about to do any of the minor operations of surgery would desire, also a bottle of wine and glasses.

The operator, in addition to the things already provided, laid out three pieces of lint, about one and a half to two inches square, with quite a small hole in their centre, three pieces of lint, and three pieces of tape bandages, also a case containing a knife and tongs, or forceps, which latter serve the purpose of constricting forceps and also a shield to protect the glans penis.

Everything being ready, the child was brought in upon a pillow, the god-father, having seated himself upon the table, received the pillow upon his lap with the head of the child towards his body. The Rabbi sat in front of the child, and began a recital or chant in Hebrew, and the others present who were able to do so responded. While the Rabbi was chanting he raised the clothing of the child, opened the diaper, wound the corners of the latter around the limbs of the infant, and then gave them to the god-father to hold. The foreskin of the penis was now seized and drawn well forward, then the tongs or forceps forced well down upon it, care being used to prevent the frænum from being constricted in the slot of the instrument, so, as the Rabbi told me afterwards, to have less hemorrhage. The tissue on the outer side of the tongs or forceps was now cut away with a sweep of the knife and the tongs removed when it was seen that the mucous membrane had not been removed at all. He uncovered the glans by grasping the free edge of the mucous membrane with the thumb and finger of each hand and tearing it backwards. The hemorrhage was considerable and in order to check it the operator took wine in his mouth, and then the penis of the child and held it there for a few seconds, then spit out the wine; this was repeated three times. This completed the operation, and during the dressing the chant was resumed.

During the operation a man stood at the left of the Rabbi with a teacup in his hand containing wine in which he dipped a sugar-teat; his duty seemed to be to strangle the child, if possible, by forcing this dripping sugar-teat into the mouth every time it opened it to cry. The dressing of the penis, etc., was quite complicated, the glans was first forced through the holes in the square pieces of lint before mentioned, then the lint bandages and the tape bandages outside of them, so by this time it made quite a respectable bundle. The napkin is now put on and confined by winding around the child's limbs and tucking in the ends. Then the limbs are wrapped separately in napkins and being placed side by side and extended, a thick napkin is put around them and pinned quite tight, the reason given being that it prevents the child kicking and disarranging the dressings.

DR. WILLIAMS read a paper entitled

#### MOSES AS A SANITARIAN.<sup>1</sup>

DR. MARTIN agreed as to the great sanitary value of circumcision. In youth a long prepuce leads to masturbation. A case was referred to by the speaker of a prematurely old man, with very long prepuce and extremely irritable glans penis when circumcision afforded the very best of results in about two months. We have been too dainty and have permitted this subject to drift into the hands of charlatans. Moses' only method to accomplish so great a sanitary measure for a whole people was by the instrumentality of religion. Circumcision is important in any climate and especially so in a warm climate.

When Dr. Martin was in Washington, last summer, Dr. Billings showed him a communication concerning a foreign sect, which practiced destruction of the male genital organs, leaving only a portion of the urethra as an aqueduct; they also practiced lacerations of the female genital parts.

DR. JOS. STEDMAN offered the following motion, which was seconded and carried affirmatively:—

*Resolved*, That Dr. Williams be requested to furnish the Secretary with a copy of his interesting paper on Moses as a Sanitarian, for publication in the BOSTON MEDICAL AND SURGICAL JOURNAL.

#### STATED MEETING OF THE GYNÆCOLOGICAL SOCIETY OF BOSTON.

H. O. MARCY, M. D., SECRETARY PRO TEM.

FIRST Thursday, NOVEMBER, 1881. WM. G. WHEELER, M. D., president, in the chair.

EPHRAIM CUTTER, M. D., of New York, read the paper assigned for the day. —

#### IODOFORM AND ITS USES IN GYNÆCOLOGY.

He first referred to its physical and microscopic characters, — the form of its crystals, which are hexagonal, Greek-cross shaped, and many-barbed, explains the fact of the difficulty with which it is removed from the clothing. It contains ninety-five per cent. of iodine, is a teriodide of formyl, and an analogue of chloroform.

The reader then proceeded to give an account of his twenty-five years' experience with the agent. In 1865 first applied it to an old, irritable, syphilitic ulcer of the leg, size of half dollar, edges vertical, the pain of which destroyed sleep. A teaspoonful of iodoform in powder was placed in the ulcer, and the whole covered with adhesive lead plaster. In four days two thirds of the ulcer was healed, and presented a smooth, sound surface, even with the surrounding skin. This experience led the writer to prefer iodoform in powder, as applied in gynecology, to its union with cocoa butter in suppository form. But the great obstacle, both with physician and patient, is the odor. This is overcome by the use of absorbent cotton. The iodoform is applied through a speculum, and retained by a pledget of the cotton. Professor Munn's instrument was mentioned as a convenient applicator. Another method employs the vaginal insulator of Dr. Stevens, of Charlestown. This the patient can use herself. (The instrument was shown to the Society.) A third mode, and one recommended, was the capsular method, the

<sup>1</sup> Vide the JOURNAL, January 5, 1882, page 90.

iodoform being inclosed in Planten's gelatine capsules. Here, also, the absorbent cotton packing should follow. The moment any odor is perceived the pledget must be removed, and a fresh one substituted. These capsules can be filled and applied by the patient. This is a great advantage in practice, as it saves time, is more agreeable to the patient, and renders frequent applications possible. Samples of Parke, Davis & Co.'s capsules filled were shown, containing seven and one half grains, fifteen grains, thirty grains, and sixty grains each. It is an advantage to have the apothecary furnish the filled capsules, as thus the remedy is kept odorless.

The lesions in which iodoform has been chiefly used by the author are vaginismus, hyperplasia, metritis, subinvolution, ectropium, versions, flexions, and prolapsus. In uterine hyperæsthesias and anesthetics the use is not indicated. The ground was taken that the hyperæsthesias (over-sensitiveness, the irritation of Hodge, etc.) constituted a diseased condition, to be treated with iodoform whether complicated or not with other uterine lesions.

CASE I. An illustrative case was cited, of cancerous infiltrated ulceration of the cervix that had improved under iodoform, but finally died; details as follows:—

Mrs. A., fifty years of age, resident of Louisiana, pronounced by eminent authority in New Orleans to have cancer. In summer of 1877 was treated with iodoform in half-drachm powders, applied with cotton through a speculum, twice a week for three months, to the enlarged, bleeding, lacerated cervix. The pains were destroyed as by magic, the bloody discharges abated, there was marked improvement in physical and rational signs. Patient in three months returned home, calling herself cured, but not with the approval of the writer. The treatment was neglected, relapse then occurred, and death ensued in nine months after return home. The decided curative powers of the drug in this and allied cases gives it a high rank in therapeutics. Of course, had the patient recovered, the diagnosis must have been reconsidered.

CASE II. Mrs. B., cachectic, presenting general malaise, ectropium, with infiltration, nodular thickening, and ulceration of the cervix, marble-like and dense tumors in the post-vaginal cul-de-sac, sharp, tingling, remittent pains, profuse, ichorous, foul-smelling discharges. Father died of cancer of the stomach. Maternal great-grandmother died of cancer of the breast. Iodoformization per vaginam and the Salisbury plans for cancer were followed by a cure which has remained some four years. It would be unwise to call this case cancerous, still its appearance was very suspicious, and had the patient died it would have been so considered. The iodoform acted, as in first case, in abating discharge and pain.

CASE III. Miss C., hyperæsthesia of the vagina and uterus, fetid discharge of intra-uterine origin; at first supposed to have a pelvic fibroid. After the use of iodoform in capsules, kept up for more than four months, the discharge diminished, the enlargement and sensitiveness were reduced, and now a more thorough examination revealed a left latero-flexion of the uterus, the whole organ being mobile. The patient improved in all respects but one, amenorrhœa. This was attributable to the iodoform used in large quantity and for a considerable time.

CASE IV. Hyperplasia, hyperæsthesia of vagina and uterus, abdomen enlarged laterally, chronic metri-

tis. Patient fifty years of age, multiparous, still menstruating. Pain in walking at every step; numbness in both legs and feet, but still could distinguish points one half inch apart. Uterus too sensitive for examination. Use of iodoform, rest in bed, and strict diet relieved the symptoms in a few weeks.

In a late work the writer has emphasized the necessity of preparing patients for pessaries<sup>1</sup> in cases of hyperæsthesia, complicated or not. Reliance was laid on depletion to produce *agathesia* (*ἀγαθός* and *αἰσθησία*), good feeling. Since then he had determined and stated that iodoformization realized this result in a much better manner. The disregard of the removal of hyperæsthesias had brought undeserved reproach on mechanical treatment.

CASE VI. Miss S., virgin, thirty-four years of age, in consumption (pretubercular stage); complained of general languor and prostration, not justified by the amount of lung disease. This was traced to vaginismus and retroversion. Iodoformization in fourteen days reduced sensitiveness to such extent that a Cutter retroversion loop pessary was readily applied, and comfortably worn, with relief. Without iodoformization the case could not have been thus treated.

The author stated that one patient has worn the Cutter Stem Pessary for five years consecutively for prolapsus of the ovary, with relief. In another subject this pessary has been worn for four consecutive years. These cases confute the assertion of some of our most prominent authorities who deny the possibility of the safe use of any stem pessary. The barriers to its use have been lessened by the iodoformization, of which the following case is typical:—

CASE VIII. *Severe vaginismus, anteversion; iodoformization, stem pessary, eight months' use, followed by relief. Restoration of embonpoint, vivacity, and enjoyment of social life.*

Virgin, twenty-four, pale, feeble; fond of dancing, but unequal to the labor involved. Menstruation very painful. Father died of consumption. After iodoform application the uterus was replaced, and fitted with a Cutter anteversion pessary. Did well for a time till anteversion over the loop of the pessary occurred. The stem pessary was next applied, and has been worn over eight months. Society engagements have been entered upon; patient has taken a considerable journey. Personal appearance much improved.

One case was related where iodoform seemed to produce abdominal discomfort, which ceased on its disuse.

It was stated that some preparations of iodoform have been found to occasion stinging pains, a condition just the reverse of its normal action. The cause of this has been sought for in vain; it had occurred to the observer that in such instances the crystals were dense and sharp to the feel, in place of the smooth, unctuous, talc-like feel of the iodoform of standard make (that is, that of Billings, Clapp and Co., Rosengarten and Son, and others).

Is iodoform absorbed? A case was cited where a capsule of iodoform was inserted into the rectum of a patient who was wholly ignorant of its physical properties; this patient made bitter complaint of the taste perceived in the mouth. No attempt was made to explain the action of iodoform as a sedative and local anæsthetic.

<sup>1</sup> Contribution to the Treatment of Versions and Flexions of the Unimpregnated Uterus. Boston: J. Campbell. (1877.)

A quotation followed from the letter of a patient, dated October 14, 1881, as follows: "I have had iodoform applied all of the time. I do not think it is possible for any one to have less trouble from the use of it than I have had. I wear the capsule and cotton a week without removal, and do not experience any unpleasant odor only as it is inserted and removed. I do not think I could walk as much as I do if it were not for the iodoform."

The author insisted that iodoform deserved a good deal of consideration from gynecologists, for certainly in his practice it did what no other drug or procedure has so well done, and concluded by quoting a note from Professor Mundé, in which he says he has been "very well pleased with iodoform in cervical ulceration (ectropium) and chancreoids, and in these applications I quite agree with your experience. I still farther have had excellent results with it as a local anæsthetic in utero-pelvic trouble."

DR. WARREN criticized the writer's inference that some of the cases reported might be of malignant character, and observed that movability of vaginal tumors, mentioned once or twice, was presumptive evidence that such were not malignant, as one of the first evidences of malignity was fixation and infiltration into the surrounding parts.

DR. WHEELER had used iodoform with satisfaction as an alternative stimulant to ulcerating surfaces, and believed it to have great value.

DR. CHURCH, present by invitation, reported a case of ulceration of the extremities, where marked improvement had followed the use of iodoform. The patient complained of its producing a distinct taste in the mouth. There was also a suppression of the menses. However, for other causes, the patient only survived a few months, and the amenorrhœa was very likely occasioned by exhaustion. This observation, however, suggested the inquiry whether the drug might exert an influence in producing amenorrhœa.

DR. MARCY had used iodoform with satisfaction upon ulcerating surfaces. He believed it was an antiseptic and referred to the remarkable report of Professor Eschmarch, in which he gives the results of nearly four hundred major operations, in which dependence was placed upon this remedy. Of the entire number there were only six deaths, and eighty-five per cent. of the cases cured were healed by first intention with one dressing. These included one hundred and forty-six excisions of large tumors, forty excisions of mammae and axillary glands, fifty-one major amputations, eight herniæ, forty-nine compound fractures, etc. The cases were all dressed with pads soaked in iodoform and absolute alcohol (ten per cent.), fastened on by an iodoform bandage, over this a large pillow of jute and gauze, a moist dressing, and over all the elastic bandage.

Iodoform was used and valued more in Europe than in America. He expressed surprise at the large quantities used by Dr. Cutter, and asked what necessity or gain there might be in such practice, and, further, if such use had ever been followed by dangerous or unpleasant symptoms. Frequent applications, as reported, by the teaspoonful, at least made it an expensive remedy.

DR. CUTTER, replied that he had never seen injury follow from the prolonged employment of large doses of this agent.

DR. GARRATT testified to his success in the use of iodoform. Some preparations are unreliable. Ex-

pressed his belief that the devitalization of the tissues was one of the most common causes of tumors or any other pathological change. Iodoform is undoubtedly absorbed and acts as a builder of tissues; and hence its value.

The doctor reported a case of uterine fibroid tumor so large as markedly to disfigure the patient, and of rapid growth; this he had had under observation and treatment since last December. Had given perhaps fifty applications of forty elements, continuous current, for from ten to fifteen minutes every second day. The tumor has now entirely disappeared.

DR. J. H. WARREN, present by invitation, had found iodoform of much value in fissures, fistulas, buboes, etc. He reported the odor as much less disagreeable when the drug was mixed with one tenth its weight of tannin or when dissolved in alcohol. In his experience, electricity had been of very little value in the treatment of fibroids. Had also tried Dr. Newson's (Philadelphia) plan of the dry earth treatment without benefit. He recognized the fact, however, that fibroids frequently degenerated spontaneously, and may lessen in size or disappear, — hence the supposed benefit of a remedy used at the time.

DR. STEVENS remarked he had found a very convenient method of use to be to combine iodoform with a small proportion of pulverized gum tragacanth, then moisten and roll into convenient size, making a bougie.

DR. NELSON had seen satisfactory results follow the use of iodoform in chronic suppurative diseases of the ear, and believed it of much value as a local stimulant as well as having the power to arrest decomposition.

DR. TWITCHELL, of Keene, N. H., had observed good results follow resort to the remedy under discussion, and believed, within certain limits, its use was to be recommended.

DR. GARRATT exhibited to the Society his device for the refrigeration of President Garfield's sick room. It consists of a blower forcing air through an ice-chamber, which thus not only cools the air but condenses moisture and gives a continuous cool and dry current. The simplicity and efficiency of the apparatus was favorably commented upon by all.

## Recent Literature.

*The Diagnosis and Treatment of the Diseases of the Eye.* By H. W. WILLIAMS, Professor of Ophthalmology in Harvard University. Boston: Houghton, Mifflin and Company. 1881.

Most of this book is excellent. It is not designed for the professional ophthalmologist, nor for him who is trying to become a specialist in that field, and must be looked at from the point of view of the general practitioner and the student.

For the practitioner it will be of great use in keeping up his knowledge of the subject, and in showing him what cases he had better send to the specialist. It will enable the student better to understand this branch of medicine, and will give him something better to refer to than the more or less imperfect notes he may have taken during his course of lectures.

The book presents to us in a very clear manner the knowledge of a skillful specialist. Few medical books, if any, that we are acquainted with are written throughout in a more agreeable manner.

The former method of making a medical text-book was by compiling a kind of dictionary, in which certain symptoms having been classified together, the appropriate remedies were placed opposite. This simple way of calling a collection of symptoms a disease made medical education a very easy thing.

Increase in our knowledge has shown us the uncertainty of symptoms. They are not expressions to be learned by heart and recited, as it were, at the bedside. The great object in medical instruction to-day is to teach the student to weigh and judge the symptom. If any one were to search in the book before us for the positive treatment of any given case he would probably be disappointed. On the other hand, the better educated and more experienced the general practitioner is, the more willingly, and with greater profit and pleasure, will he, do we believe, consult this volume. It would be difficult to pick out the best chapters.

Whatever belongs to natural phenomena and treatment is clearly described. Much less so what pertains to the physics of the eye and the mathematics of accommodation. This subject belongs properly to physics, but it would be a great benefit to most professional men if it could be put before them in so clear a way that they could understand it without having to take up again the whole study of dioptries. In the book before us there is too little explanation to enable the general student to get through this part understandingly and without loss of time. It is easy to explain a thing to him who understands it, but for him who wants to learn it is of the greatest importance that all statements should be put in so clear a form that there could be no hesitation as to their exact meaning.

For some instances where this is not the case, take Chapter XVII., on Refraction and Accommodation. On page 334, we read: "Every convex lens has a principal focus." It should read, has two principal foci. They are both mentioned six lines lower down.

On page 334, "The visual and optic axes cross each other at the nodal point." But what is the nodal point? On page 336 it is stated that the nodal point "is the union of the two nodal points." Also that the nodal point is nearly the optical centre of the eye. We know what the optical centre of a lens is, but what is the optical centre of the eye? On page 336 it is said that the power of lenses is expressed "by fractions, of which the numerators are one and the denominators the focal distance in inches, or in the metric system, in dioptries." This phrase is obscure. The meaning of the word dioptric, as used here, is not given till page 360. It is a lens the focal length of which is one metre. The phrase does not mean that the denominators can be expressed in dioptries. For those who do not know what a dioptric is, and that is by far the greater number, the phrase should read, "by fractions, of which the numerators are one and the denominators the focal distance in inches, or, if we use the metric system, by dioptries." On page 336, "the principal point is just posterior to the cornea;" but what is the principal point? On page 334, "The distance of this point of intersection from the optical centre of the lens is the focal distance or length, when the index of refraction is 1.5', and corresponds very nearly with the radius of curvature of the lens." This is obscure. It does not mean that the distance is the focal length when the index of refraction is 1.5. But that when the index of refraction

is 1.5, the focal distance corresponds very nearly with the radius of curvature of the lens.

Many physicians, who are not ocnlists, want to get a general idea of the laws of accommodation, and will naturally look for information on that subject to this text-book, and will not find what they want.

The book is very well printed. Some of the diagrams, however, have a blurred look, and we miss an anatomical chart of the eye.

---

*A Hand-Book of Uterine Therapeutics and of Diseases of Women.* BY EDWARD JOHN TILT, M. D. New York: Wm. Wood & Co. 1881.

This is the November issue of Wood's Library of Standard Medical Authors, and, like most of the others of the series, presents some valuable material in a cheap and attractive form.

Dr. Tilt has a decided leaning toward the old school of uterine pathology, of which Bennett is the best-known exponent, which would consider inflammation the great pathological factor. That being the case it is not to be wondered at, that at least half the book is taken up with the consideration of various classes of remedies, such as sedatives, antiphlogistics, caustics, and emmenagogues, to the crowding out of the full discussion of the methods of minor gynecological surgery, which modern pathology and more perfect methods of examination have made so valuable. Hence, in this respect, the work before us will not commend itself, to the American medical man at least, especially as the part of the field so imperfectly covered here has been so well and thoroughly gone over in a work of nearly the same import by Dr. P. F. Mundé.

There is, therefore, a marked difference in the value of the several chapters. Those that relate to general treatment, such as Chapter III., on Uterine Dietetics and Home Treatment, and Chapter XIV. on Prevention of Diseases of Women, are excellent, while such as deal with more special subjects, as Chapter II., on Uterine Surgery, and Chapter XI., on Treatment of Uterine Displacement, are scanty and behindhand.

Too much attention is paid to the treatment of symptoms as such without attempting to ascertain their cause, a result which follows naturally from the neglect of the more exact methods of examination in use here. Special points for more extended criticism might easily be selected, but enough has been said to show the general tenor of the work. It will hardly take rank with the best gynecological literature of the day.

---

—The Executive Committee of the late International Medical Congress recently appointed a deputation to wait upon the Secretary of State for the British Home Department to present to him the following resolution: "That this Congress records its conviction that experiments on living animals have proved of the utmost service to medicine in the past, and are indispensable to its future progress. That, accordingly, while strongly deprecating the infliction of unnecessary pain, it is of opinion, alike in the interests of man and animals, that it is not desirable to restrict competent persons in the performance of such experiments."

# Medical and Surgical Journal.

THURSDAY, FEBRUARY 9, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5 00 a year, including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY, No. 4 PARK STREET, BOSTON, MASS.*

## MEDICAL EXAMINERS AND CHEMISTS.

THE article in our issue of January 26th, by Dr. E. P. Miller, upon the above subject, has suggested to us a few points of importance with reference to consultation with chemists in medico-legal cases. In by far the majority of cases the services of the chemist are required where an unjust suspicion has fallen upon an innocent person, or a suspicion exists in the mind of the neighboring public that a person has been poisoned without blame being attached to any particular individual, and public opinion is so strong as to demand an investigation. We have been cognizant of a large number of cases in which sudden death has occurred during the progress of some chronic disease, such as phthisis or paralysis of different forms, and in which the pathologist has been unable to state with certainty from the post-mortem appearances that the disease had been the cause of the sudden death, and at the same time a suspicion has existed that the invalid had been hurried off of the world by the administration of a poison. In such instances the negative results obtained by the chemist are very satisfactory to all of the officers, both medical and legal, connected with the case, by setting at rest rumors which had an insufficient foundation, and which, if allowed to remain in circulation without an investigation, must react to the injury of an innocent person. This class of cases, we believe, constitutes the majority of those which are submitted to the chemist, and very properly so, because there is no better way of assisting justice than by proving that no crime has been committed.

On the other hand there is another class of cases, fortunately few in number, in which the negative results obtained by the chemist are unsatisfactory, because no poison can be detected when poison was administered. The most frequently occurring cases belonging to this class are those in which there has been administered to an infant or child a dose of some preparation or principle of opium just sufficient to prove fatal after the lapse of a number of hours, when all of the opium has been entirely removed from the stomach by absorption, and most of it has either been eliminated or destroyed, the remainder, which is distributed throughout the body, being in such a minute quantity in any organ as to render detection by chemical analysis absolutely impossible. In accidental cases of this kind the negative result may almost always be predicted with certainty and the services of a chemist are not required, but in cases of

skillful criminal poisoning of this nature the negative result of the chemist is very unsatisfactory, because it may help the escape of a criminal.

Cases which, at the time of the first investigation by the medical examiner, appear to be evidently cases of suicide by poisoning, should always be investigated by a chemist because it can never be foretold how soon new evidence will be obtained which will point rather to murder than to suicide, and, in case a murder trial does result, the proofs of poisoning are rarely complete without the chemist's evidence.

If the chemist employed in a case of suspected poisoning be a toxicologist in every sense, he may often by his preliminary examination assist the medical examiner in other respects than by the mere detection of the poison by chemical analysis. For instance, by his microscopical examination of the contents of the stomach and intestines he is sometimes able to throw light upon the character of the food last eaten by the deceased and upon the time of death, questions which are sometimes of vital importance in legal cases, where these data cannot be obtained by other means of information.

## THE BOSTON DISPENSARY; ITS WORK AND ITS WANTS.

THE annual Report of the Boston Dispensary demands this year a more than passing notice. The statistics contained in it were published in the JOURNAL several weeks ago, and it is unnecessary to repeat them, but we wish to draw attention in a general way to the work of the Dispensary in the past, and its needs for the future.

It was established in 1796, and its first investment of funds in December of that year was seven hundred dollars in United States six per cent. stock, which cost \$603.75. In 1801 the Rev. Samuel Parker (rector of Trinity) and others were incorporated under the name of the Boston Dispensary. The original incorporators included twelve of the most respected citizens of Boston, and from the day of its institution to the present the list of its managers comprises the names of influential gentlemen who have taken pride and satisfaction in ministering to the wants of that class for whose benefit the institution was founded.

Of the exact method of dispensing its charities in its earliest years little is known, save that it was found "essentially useful!" but in 1802 the town was divided into three dispensary districts, and there were annually chosen three attending and two consulting physicians. In 1813 the list of physicians who had given their services was as follows: As consulting physicians, James Lloyd, Isaac Rand, John Warren, Aaron Dexter; as attending physicians, John Fleet, Isaac Rand, Jr., John Dixwell, James Jackson, J. G. Coffin, Horace Bean, Thomas J. Parker, John Gorham, Cyrus Perkins, S. R. Trevett, Asa Bullard, Wm. Gamage, Jacob Gates, Jacob Bigelow, John Revere, and since that time most of the medical men who have risen to eminence in Boston have at some time been members of the Dispensary staff. Much the same

general plan, with a gradual increase in the number of districts, was followed up to the year 1856, when it occupied one half of the present house on Bennet Street, and in addition to its house visitation established its central office, where, in the words of its Report of that year, all poor patients shall, at certain hours daily, be gratuitously prescribed for and treated by gentlemen of the medical profession, whose names will insure the confidence of patients as well as of those who are interested in the welfare of the sick poor of the city. It has now for many years occupied the whole of the double house originally purchased, and its rooms have been all occupied by a gradual increase in the number of its physicians, made necessary by the growth of the city and the establishment of special departments.

Few institutions do the same amount of work so quietly or with such an absence of display. Indeed, one of its aims from the first seems to have been to maintain that divorce between the knowledge of the left hand and the action of the right which is especially enjoined, as one of the particular advantages which its founders promised themselves from their association in the work was "that those who have seen better days may be comforted without being humiliated, and all the poor receive the benefits of a charity the more refined as it is the more secret."

So unobtrusive have been its works that no mention is made of them in the chapter on the charities of Boston in the recently completed *Memorial History of Boston*.

No one who has seen anything of its workings can doubt their value to the poor themselves, and its benefits are by no means confined to the recipients of its charity. As an institution for medical work it has been a valuable means of educating the younger members of the profession, and has, without doubt, raised the standard of medical attainments, and thus proved a blessing to rich and poor alike.

"It is not to be supposed that the motives of the attending physicians have been wholly foreign from considerations of personal advantage. They have doubtless been actuated by the hope of professional improvement, and the prospect of building up an honest fame as well as by the desire of fulfilling the benevolent intentions of this charity.

"These incitements, however, are so worthy and commendable, and their duties, now become laborious, have been performed with such assiduity, with so much of the spirit of charity, that these gentlemen have well deserved the thanks of the friends of humanity, and have earned for themselves an honorable distinction."

In 1813 the Dispensary had attended 8500 patients, and the apothecary kept a "fair record" of the name of each patient, and of the contributor by whom said patient had been recommended, and the Dispensary provided that "each physician shall be furnished (if not already so) with an injecting syringe and cupping machine, to be transmitted to his successor on leaving the office; and said physician may furnish medicines, in cases of necessity, at the expense of the institu-

tion, not exceeding ten dollars annually; and a stomach pump, for general use, shall be deposited with the apothecary."

In a single year (1881) there were treated 26,113 — a marked falling off from previous years, but more than three times as many as during the first seventeen years of its existence. And though its central office is still known by the sign of the Good Samaritan its methods and its needs have changed with the change in numbers and character of the population.

The "large, substantial, and commodious brick houses" of 1852 are in 1882, with its increased work, no longer large, and most decidedly ill-ventilated. Two hours' waiting in its crowded rooms means headache and exhaustion to the physician, and equally affects those it is sought to benefit. Its special departments are crowded, and as a whole it is illy adapted to the work it has to do; so the managers have now decided to appeal to the public and to those friends who have always been interested in the care of the sick and deserving poor for aid in their endeavor to provide more ample room. The managers trust that the benefits conferred by this institution upon a numerous body of sufferers in past years will awaken a new desire in the public mind to improve its facilities for greater usefulness, and that their appeal for an increase of funds will be generously responded to by those persons in our community who wish to aid the deserving poor.<sup>1</sup>

It would be impossible to estimate by any ordinary standard the amount of good actually accomplished by this institution. The most radical reformer of our charity systems admits the necessity of assisting the poor when disabled by sickness, and even the vicious become objects of pity when helpless from accident or disease. Our foreign missionaries find it advisable to call in the doctor's assistance in winning their way in heathen lands; it is just as proper to employ his services among the wretched at our own doors. Many as are the objects appealing for aid we know of none more deserving; the very modesty of its work is shown in the silent method it has so far employed in asking assistance. We have no desire to have it depart from its self-imposed rule of comparative silence in regard to its deeds and its wants, but the very quaintness tempts us to quote from an old appeal made by one of its managers in 1813:—

"It would be difficult in my judgment to conceive a plan of beneficence better entitled than the one before us to the public patronage; to the bounty of the rich, the services of the active and benevolent, and to the good-will and sympathy of those who have nothing else to offer. This is not that promiscuous giving, which with pure motives sometimes produces immoral effects; it is a specific appropriation for a definite, humane, and laudable object. He who communicates of his substance to the poor, of his benevolence to the affections of others, hereby enlarges that sublime enjoyment which malignant or selfish minds can neither participate nor conceive."

<sup>1</sup> Report, 1881.

## MEDICAL NOTES.

— At the Councilors' meeting, February 1, 1882, Sir James Paget, of London, England, was elected to honorary membership in the Massachusetts Medical Society.

— By the will of the late E. W. Stoughton, former United States Minister to Russia, the sum of two thousand dollars is left to the Medical School of Dartmouth College to complete a collection in the pathological museum founded by him.

— The Boston Medical Library Association has recently received by a codicil to the will of his daughter, lately deceased, a very admirable and valuable portrait of Dr. John Williams, of Cambridgeport, by Miss Stuart. Dr. Williams joined the Massachusetts Medical Society in 1812, became a retired member in 1827, and died in 1846 at the age of ninety-nine.

— The following interesting extract is from a recent report of the British Medical Association Benevolent Fund. "The fund was established for the relief of medical men in temporary difficulty or distress, and for their widows and orphans; and also for granting annuities to those who are quite incapable of providing for themselves after sixty years of age. It was originally founded, forty-seven years ago, by the Provincial Medical and Surgical (now the British Medical) Association. In the administration of the fund there are no salaries nor office expenses. The entire administrative expenditure, including collector's commission, the printing of the report, postage and stationery, amounted to a little over £100 in 1880. Much of the distress which the donation department is called upon to relieve is capable of alleviation only; the applicants are in absolute poverty, and unable, from ill-health or incapacity, to do anything towards their own maintenance, and the aid given helps to keep them from starvation or from the workhouse. In other cases a widow or daughter is maintaining herself and, perhaps, a family, by teaching, or by letting lodgings or keeping a shop, or by acting as nurse, or by needle-work or work with a sewing-machine. The earnings fall short from some cause or other, and timely assistance saves a deserving, hard-working woman from falling into hopeless misery. Again, no year passes in which some widow left utterly unprovided for, often with children, does not come to the fund in the early days of her bereavement. From time to time a medical man, broken down by misfortune or illness, is driven to seek the aid of the fund. During forty-one years, up to the end of 1880, 3,144 grants of immediate relief were made to applicants, at a cost of £29,786, thereby relieving much misery among the destitute members of the profession and their widows and children.

— The following item in regard to Samuel Piercy, the actor, who died of small-pox in this city a short time ago, is copied by the *Boston Advertiser* from the New York correspondence of the *Philadelphia Press*: "He was one of a half-dozen intelligent men I ever knew to be influenced by the crazy howls of the anti-vaccination fanatics. Jebb and Bergh and the rest of the mistaken lot had managed to convince him that

the risks lurking in the preventive were worse than the dangers of the disease. Before leaving New York, a few weeks ago, he laughingly rejected the advice of friends who urged him to be vaccinated. He was a pervert to the views of Jebb and Bergh, and he paid the penalty of martyrdom."

— At the last meeting of the New York Academy of Medicine a paper was read on Practical Points in Plumbing. The president, Dr. Fordyce Barker, opened the meeting with an address, and after the paper by Mr. Charles F. Wingate various sanitary evils were discussed by the members present.

— The Canterbury Small-Pox Hospital contained seven patients on Tuesday last.

— The *Toronto Medical Journal* appeals to the profession of that city to found a library and directory of nurses, in accordance with the plan of the Boston institutions of the same name.

— The twenty-first annual meeting of the contributors to the Women's Hospital of Philadelphia was held lately in the hospital building, Twenty-Second Street and North College Avenue.

The report of Dr. Anna E. Broomal, physician in charge of the hospital, gave the following statistics: Number of patients admitted during year, 311; patients attended at their homes, 4375; prescriptions compounded for dispensary patients, 15,869. The in-patients embraced persons of all nationalities. In the obstetrical department 92 patients were admitted during the year; retained from previous year 2, making a total of 94 patients. Discharged well, 85; deaths, 3; remaining, 7.

In the training school for nurses 31 pupils were admitted; of this number 7 left the class at or shortly after the month of probation; 4 nurses received diplomas, and 20 are still training.

## NEW YORK.

— The report of the Night Medical Service, submitted to the Board of Health, shows that during the sixteen months of its existence, from September 1, 1880, until January 1, 1882, 573 calls have been made. These were distributed among 132 physicians out of the 450 whose names appear upon the roll. The Tenth Precinct, embracing a large tenement-house district lying east of the Bowery, has afforded more calls upon the service than any quarter of corresponding area in the city. The majority of the cases treated have been of a very urgent description, comprising 57 night attacks of croup, 28 of pneumonia, 10 of pleurisy, 55 of confinement, two of gunshot wounds, 11 fractures and dislocations, 15 suicides, and three cases of accidental poisoning. Of all the calls made only 19 were able to pay the fee specified by law, and in the remaining 554 the appropriation was called upon. Notwithstanding this small percentage of pay cases only \$1,662 has been expended in the actual payment of medical men, with a small amount for printing blanks and other incidental expenses.

Dr. Ewing, the Superintendent of the Bureau, has been at great pains to investigate each case where there was a possibility that the patient might be able to pay, and he is satisfied that very few have escaped

him. The small percentage of pay cases he attributes to the fact that the majority of the calls have come from the poorer classes, and not to any evasion or dissimulation practiced by those whose names have been reported as having availed themselves of the provisions of the law.

—The English Society of St. John of Jerusalem, which has been very active for the past five years in educating people in the care of the sick and wounded, is to be copied in a modified form. The new Society bears the name of the Society for First Aid to the Injured.

#### PHILADELPHIA.

—By a decision of the court, the conveyance of the tract of land to the University has been confirmed.

—A University Club has been instituted in this city, and has rented a handsome house on Walnut Street near Broad. Caud dates must have a University degree. It promises to be quite the rage among medical men especially. Bishop Simpson is President for this year. The register is now said to contain about four hundred names. Overtures have been made to the University Club of New York to exchange hospitality to members of the clubs visiting either city.

—Dr. Frank Woodbury has resigned his position as Reporting Secretary to the Philadelphia County Medical Society.

### Miscellany.

#### THE PERIOD OF GESTATION AND THE PLACENTA OF THE ELEPHANT.

THE birth of a young elephant, at Bridgeport, is the second well authenticated instance of such an occurrence in captivity on record, a previous birth having taken place in Philadelphia in March, 1880. Professor Owen, of London, in Vol. III., page 742, of his *Anatomy of Vertebrates*, mentions still another instance as having occurred August 3, 1865, the elephants having paired December 18, 1863, but does not state where the birth took place nor does he cite any authority in reference to it. Prof. H. C. Chapman, of Philadelphia, who, from his connection with the Zoological Garden there and his interest in comparative anatomy, had an opportunity to follow events in the case of the elephant Hebe from the first suspicions of pregnancy to parturition, made an interesting communication to the Academy of Natural Sciences, of Philadelphia, to be found in Vol. VIII., of its journal, upon the placenta and generative apparatus of the elephant, presenting at the same time the injected placenta.

In the case of Hebe the first coitus took place May 29th and the last June 20, 1878; eight months later, there being good reasons to consider her pregnant, the question of the period of gestation arose, in regard to which we quote from Dr. Chapman's paper: "Here again I was comparatively in the dark. In the *Thesaurus of Seba*, published in 1734, there is figured the fetus of an elephant without any membranes taken out of its mother at about the middle of the period of gestation. Zimmermann also gives a figure of a fetus. In the description of this fetus only vague allusions are

made to the length of gestation. As is well known, among the ancients, Pliny thought the period of gestation was six months, Strabo about eighteen; according to Aristotle, however, nearly two years.

"What I had learned from travelers in the East and from the case referred to by Professor Owen, the time being in that instance five hundred and ninety-three days, together with the fact of Aristotle giving nearly two years, led me to indicate that about the first of March, 1880, would be the time at which the birth of the elephant might be looked for. The young elephant was born March 9th, exactly twenty months and twenty days after the last copulation, or twenty-one months and fifteen days reckoning from the first one. The fixing of the period of gestation in the elephant at six hundred and thirty to six hundred and fifty-six days is another interesting illustration of modern investigation confirming the statements made by that most profound thinker and careful observer, Aristotle.

"The labor was a very short one, the mother standing on all fours, with one hind foot slightly raised. The head presented. The umbilical cord broke, and was removed with the placenta and membranes shortly afterward by Mr. Arstingstall. Immediately after birth the mother rolled the young one in the straw. The young elephant, a female, stood thirty inches in height, measured from base of trunk to root of tail thirty-five inches, and weighed two hundred and thirteen and one half pounds. It was noticed immediately that it sucked with the mouth, and not with the trunk, as Buffon reasoned it must do. . . .

"The placenta of the elephant is not only interesting on account of its rarity, but also from its combining the characters of the placenta of three different sets of animals. The impossibility of using the placenta, in the case of the elephant at least, as a means of classification is therefore sufficiently obvious."

The latest elephantine baby is stated to have weighed one hundred and forty-six pounds at birth, and the period of gestation, as given, was shorter by several weeks than in the case reported by Dr. Chapman.

#### LETTER FROM PHILADELPHIA.

MR. EDITOR,—The prevailing characteristics of this winter in this locality have been mildness of temperature and excess of aerial moisture, marked by sudden changes of the weather. The clear, cold, bracing atmosphere that we naturally expect at the winter solstice has been conspicuously absent, and in its place we have had more or less London fog, and damp, moist, disagreeable days that breed pneumonia and epidemic disease. The open winter has kept the streets in the most favorable and inviting condition—for the street-cleaner, but this functionary is, alas, a *non est* man, and cannot be tempted to go against the almanac, and clean the streets when they should be frozen solid according to all precedent. It is also in accordance with precedent for the contractors to regularly draw their pay for cleaning the streets in the winter without performing any labor, the snow and ice affording a good standing excuse for their neglect. Petitions in regard to the dirty condition of the streets have been addressed to councils, but without avail; owing to an unfortunate dead lock upon a political question, no appropriation could be obtained for this purpose. Mean-

while the City Board of Health undertook to do the work themselves or to insist upon its performance, and for this action the matter has been taken out of their jurisdiction entirely, and finally given to the commissioner of highways, who promises to begin about the first of February to really clean the streets. One indication that shows that systematic work is likely to be done is the order lately issued requiring the policemen now to make weekly reports of the condition of the highways. In the mean time the streets have been in a condition that is considered as most favorable for the development of all kinds of zymotic disease. Small-pox, scarlet fever, measles, whooping-cough, r  theln, have been moderately prevalent; typhoid fever claims an unusual number of deaths for this time of the year, but without appearing in an epidemic form. Small-pox appears to be declining, although deaths are still occurring. The influence of the filthy streets, taken in connection with the damp atmosphere, has also increased the number of cases of disorders of the air passages; influenza and coryza have been almost general, and pneumonia and bronchitis very common.

The college lectures are well attended, however, and the health of the students, as a rule, very good, the mild weather, apparently agreeing with many strangers better than extreme cold that we experienced a year ago.

The annual meeting of the College of Physicians was held January 4, 1882, at which the following officers were elected: Dr. W. S. W. Ruschenbeger, president; Dr. Alfred Still  , vice-president; Dr. Richard A. Cleemann, secretary; Dr. Chas. Stewart Wurts, treasurer; Dr. Thomas Hewson Bache, curator of museum; Dr. Frank Woodbury, librarian; Dr. J. Ewing Mears, recorder; Dr. Lewis Rodman, Edward Hartshorne, William Goodell, and Samuel Lewis, censors.

The Philadelphia County Medical Society, at its January meeting, elected Dr. Horace Y. Evans, president; Drs. Chas. K. Mills and John B. Roberts, vice-presidents; Dr. Henry Leffmann, recording secretary; Dr. J. D. Nash, as-istant secretary; Dr. H. Aug. Wilson, corresponding secretary; Dr. Frank Woodbury, reporting secretary; Dr. M. O'Hara, librarian; Dr. Wm. M. Welch, treasurer. A number of new members were also balloted for, making the names on the roll now amount to about three hundred and fifty. The board of censors refused to place the female candidates upon the list for election, on the plea that such an innovation involved a radical change in the rules, and would therefore require a constitutional amendment. The resolution adopted at a previous meeting declaring women eligible was not regarded as of sufficient authority without further action by the Society.

At this meeting the number of stated conversational meetings was increased to three each month, on account of the great interest lately developed by the appointment of a committee on clinical pathology, which has already had several interesting meetings characterized by the exhibition of an abundance of clinical material and of morbid specimens. In connection with this subject, it might be stated that at the regular meeting, January 11th, Dr. W. W. Keen read an admirable paper upon the   tiology and Pathology of the So-Called Dupuytren's Contraction of the Fingers, and exhibited several cases and photographs of others cured by subcutaneous section of the contracted fascia palmaris. He attributed the disorder to a general

systemic condition (allied to gout), and generally showing a hereditary tendency, and doubted the traumatic and local origin. On the same evening Dr. W. S. Little reported a case of sphacelus of the cornea (kerato-malacia) in a child with inherited syphilis, subsequently fatal.

The University of Pennsylvania has lately acquired by act of councils a large piece of land adjoining its property in West Philadelphia, which is needed to erect laboratories and dormitories. The land thus conveyed by the city was part of the almshouse grounds, and in view of its intended use, it was sold at a nominal sum. In the correspondence pending the negotiation, Provost Pepper made the following communication to a member of council:—

"Should any question be raised as to the liberality of the trustees and their friends, and the validity of the grounds on which they base their plans for the future, you are at liberty to mention that, during the past eleven months, the following contributions have been made to the permanent endowment educational fund of the University: Joseph Wharton \$100,000; Thomas A. Scott, \$50,000; John Welsh, \$10,000; A. Whitney & Sons, \$10,000; William Sellers & Co., \$10,000; C. C. Harrison, \$10,000; Fairman Rogers, \$10,000; Clarence H. Clark, \$10,000; William Pepper, M. D., \$10,000; J. B. Lippincott, \$10,000; S. Weir Mitchell, M. D., \$5,000; Eli K. Price, \$5,000; Richard Vaux, \$5,000; J. Vaughan Merrick, \$5,000, and others of somewhat smaller amount, aggregating over \$265,000."

Opposition has been made to this transfer by some who question the legality of the proceeding, and it will probably require confirmation by the courts.

A case of death from acute poisoning by alcohol is reported from the interior of the State. Owing to a railroad accident, a freight car containing some barrels of whiskey was wrecked near Brookville. A few men drank freely of the unrectified spirit and one has since died (he probably discovered his mistake too late to rectify it). It is evident that whiskey, like trichinous pork, requires to undergo certain manipulations before it can be considered wholesome (if ever).

A case of hydrophobia occurred in Camden, last week, which proved rapidly fatal. The patient, a young man, was bitten by a "Spitz" in August last. He had the wound cauterized and had entirely lost any fear of bad result after the wound had healed. On January 21st he complained of general muscular soreness which he attributed to cold, the following day he had convulsions, and on night of third day he died with the usual symptoms. This case is very much like one that occurred in this city last fall, which excited very great interest at the time on account of the painful circumstances attending it. The victim was a young gentleman who, stooping to caress a vagrant dog that came into his office, was bitten on the hand. The dog was not a Spitz; but in this case the patient was apprehensive of hydrophobia from which he perished about four months afterward.

#### JENNER'S INSTRUCTIONS FOR VACCINE INOCULATION.

MR. EDITOR.—In the London *Lancet*, February 26, 1881, there appears at length a supposed hitherto-unpublished manuscript of Edward Jenner's on Instruc-

tions for Vaccine Inoculation. The original is in the possession of Frederick Symonds, Esq., of Oxford. I have recently discovered, however, that the paper in question had been made public in America as early as the year 1802. Any one interested in the facts will find the document, exactly as printed in the *Lancet*, on page 91 of "Practical Observations on Vaccination; or Inoculation for the Cow-pock. By John Redmon Cox, M. D., Member of the American Philosophical Society, and one of the Physicians to the Pennsylvania Hospital. Embellished with a Colored Engraving representing a Comparative View of the various Stages of the Vaccine and Small-Pox. Philadelphia: Printed and Sold by James Humphreys, at the Corner of Walnut and Dock Streets. 1802." Dr. Cox, after some reference to spurious vaccine, etc., concludes thus: "On all these heads, I must refer to Dr. Jenner, p. 72 *et seq.*, and shall here content myself, with giving a valuable and concise view of the genuine and spurious pustule, in Dr. Jenner's 'Instructions for Vaccine Inoculation,' which I lately received from England, and which have already been published in the news-papers."

Very respectfully,

W. A. HARDWAY, M. D.

ST. LOUIS, January 26, 1882.

### INSANITY AS A DEFENSE.

*New York Oyer and Terminer.* November, 1881.

THE defendant, upon an indictment for murder in the first degree, admitted having shot the deceased, and claimed that she was insane at the time through wrongs alleged to have been received at the hands of the deceased.

Davis, P. J., in charging the jury, said: Insanity is usually spoken of, both in common language and in the books, as a defense to crime. But it is no defense, because where the insanity recognized by the law exists there can be no crime to defend. An insane person is incapable of crime. He is devoid, both in morals and in law, of the elements essential to the constitution of crime, and hence is an object of pity and protection and not of punishment. Therefore, whenever it is established that a party accused of crime was, at the time of its alleged commission, insane within the established rules of the criminal law, he is entitled to acquittal on the ground of innocence because of incapacity to commit the offense, however monstrous his physical act may appear. Both humanity and the law revolt against the conviction and punishment of such a person. In this State the test of responsibility for criminal acts, where insanity is asserted, is the capacity of the accused to distinguish between right and wrong at the time and with respect to the act which is the subject of inquiry. This rule is stated by the authorities in different forms, but always in the same substance. In one case it was said, "the inquiry is always brought down to the single question of a capacity to distinguish between right and wrong at the time the act was done." This was in the Freeman case, the celebrated case of the colored man who was tried for murder in Cayuga County, and defended by the late William H. Seward. In the most authoritative of the English cases it is said, "it must be clearly proved that at the time of committing the offense the party accused was laboring under such a defect of

reason from disease of the mind as not to know the nature and quality of the act he was doing, or, if he did know it, that he did not know that he was doing what was wrong." And in a very late case in our court of appeals a charge in that exact language was held to present the law correctly to the jury. The doctrine that a criminal act may be excused upon the notion of an irresistible impulse to commit it, when the offender has the ability to discover his legal and moral duty in respect to it, has no place in the law; and there is no form of insanity known to the law as a shield for an act otherwise criminal, in which the faculties are so disordered or deranged that a man, although he perceives the moral quality of his acts as wrong, is unable to control them, and is urged by some mysterious pressure to the commission of the act, the consequences of which he anticipates and knows.

Emotional insanity, impulsive insanity, insanity of the will, or of the moral sense, all vanish into thin air whenever it appears that the accused party knew the difference between right and wrong at the time and in respect of the act he committed. No imaginary inspiration to do a personal wrong to another under a delusion or belief that some great public or private benefit will flow from it, where the nature of the act done, and its probable consequences to the injured party, and that it is in itself wrong, are known to the actor, can amount to that insanity which in law disarms the act of criminality.

Having shown you the law of insanity applicable to the case, it is important that I should give you the law in respect to its proof. The law presumes sanity in all cases. That presumption in a criminal case is *prima facie* evidence of the sanity of the accused party, and where no evidence tending to show the contrary is produced, the case of the People, so far as relates to the question of sanity, is made out. The burden of overthrowing the presumption of sanity is upon the person who alleges insanity, and if evidence be given by him tending to rebut the presumption and to show insanity, then the general question is presented to the jury whether the alleged crime was committed by a person responsible for his acts, under the rules of law which have been already laid down. Upon this question thus presented, the presumption of sanity and the evidence tending to prove or disprove insanity are all to be considered by the jury, and at that stage of the case the question of sanity, like all other material questions of fact, becomes one on which the prosecution holds the affirmative, and if reasonable doubt of sanity then exists upon the evidence before the jury, the prisoner is entitled to the benefit of that doubt as upon any other material question of fact. — *The Reporter.*

### A BILL TO PROVIDE FOR SANITARY INSPECTION AND REGULATION OF PUBLIC SCHOOLS IN OHIO.

WE have received a copy of a bill known as the Block Bill, lately introduced into the Ohio Legislature, authorizing Boards of Health in cities of the first class and second grade to make sanitary inspections of the public schools and prescribe sanitary regulations. Petitions for its enactment were very generally and well signed. The value of local boards of health as regulators of school hygiene must depend upon the manner of appointing these boards.

Were the National Board of Health and the Commissioner of Education at Washington to urge this question of school hygiene simultaneously upon local boards of health and education, something might be effected towards harmonizing interests and opinions and uniting influences in its support.

The following are the provisions of the Ohio bill:—

SECT. 1. Be it enacted by the General Assembly of the State of Ohio, that it shall hereafter be the special duty of the Boards of Health in cities of the first class and second grade to make sanitary inspections of the public schools, including school buildings in such cities, and to prescribe such sanitary regulations to be observed in such schools as said Boards may deem necessary in order to preserve the health and promote the physical welfare of the scholars.

SECT. 2. In carrying into effect the object contemplated in the foregoing section of this act, any such Board is hereby authorized to appoint a professional physician having the proper qualifications, and who is not a member of the Board, to make all such sanitary inspections, and may permit him, with the approval of the Board, to employ, if need be, one or more assistant physicians, having like qualifications, to aid him in his work of inspection. And for all such services so rendered by any such principal or assistant physician, for the time necessarily employed, the Board shall allow and fix a just and reasonable compensation, which shall be levied and paid in the same manner as other expenses of the Board.

SECT. 3. It shall be the duty of the principal physician to make thorough inspections of the sanitary condition of all the public schools, including school buildings, in such cities, and also to investigate the causes which impair, or tend to impair, the health of the scholars, and prescribe the appropriate remedies and sanitary regulations which should, in his judgment, be observed in order to secure and promote the physical welfare of the scholars attending such schools, and report the same to the Board quarterly or oftener, as the Board may require, with all such statistical facts and observations as he may deem important, and which the Board shall embody in full or in substance in their annual report to the City Council.

SECT. 4. It shall be the duty of the teachers and superintendents of public schools in such cities to observe and enforce all such sanitary regulations as far as practicable in their respective schools, after such regulations have been approved by the Board of Health, and printed copies thereof furnished them by order of the Board, and also to facilitate the sanitary inspections of such schools or school buildings in their charge by giving, when requested, to the inspecting physician, or his assistant, such information as they may possess, or can obtain, relative to the sanitary condition of such schools or school buildings, and in such written form, or report, as may be required by such physician, and in case such teachers or superintendents, or any of them, shall neglect or refuse to observe and enforce such sanitary regulations, or any of them, so far as practicable in their respective schools or school buildings, he or she, so offending, shall be subject to prosecution and fine for each offense, of not less than five nor more than fifty dollars, at the discretion of the court, and all such fines, when collected, shall be paid over to the school fund of such cities.

#### INJECTIONS OF PEPTONIZED MERCURY FOR SYPHILIS.

THE fact that mercury is absorbed in the state of *albuminate* had already suggested the addition of white of egg to the solution in the hope of thus facilitating its absorption, with better, but still unsatisfactory, results. Then Bamberger proposed the substitution of peptone for the albumen. Acting upon this suggestion M. Martineau has had prepared a solution which he has employed, and he has published the result of a large number of cases of syphilis treated by the new method at the Hôpital Lourcine. The preparation employed consists of a mixture of powdered peptone, chloride of ammonium, and bichloride of mercury, which are dissolved in water and glycerine. In order to have a standard solution which shall contain five centigrammes (.02 grain) in a gramme the following por-

tions are taken: Powdered peptone (Catillon), nine grammes; chloride of ammonium, nine grammes; bichloride of mercury, six grammes. These are dissolved in glycerine, seventy-two grammes; water twenty-four grammes. This solution, which the author calls "normal," further diluted with five parts distilled water, is of such strength that an ordinary French hypodermic syringe-ful represents ten milligrammes, or a fifth of a grain of corrosive sublimate. The solution is injected subcutaneously into the back between the scapulae or in the lumbar region, on account of the cellular tissue there being loose and abundant. He insists that the needle should be sharp, and that it should enter deeply into the tissues.

The mercurial thus administered appeared to M. Martineau to act more promptly and with more effect than when introduced by the stomach, and to be especially applicable to very grave cases with threatening symptoms, where it is necessary to produce decided and prompt action. The procedure recommends itself, moreover, by the ease with which it is employed, and by the absence of pain and other bad consequences.

The dose employed by M. Martineau has varied from two milligrammes (one twenty-fifth of a grain) to ten (one fifth of a grain) of bichloride of mercury. Altogether one hundred and seventy-two patients have been under observation and a total number of 3838 hypodermic injections made. No abscesses or sloughs have ever followed the operation; sometimes a defective injection has given rise to a lump, but this has always rapidly disappeared. There is never either stomatitis or salivation, even with a fifth of a grain of the mercuric salt daily. It may here be noted parenthetically that the dose of bichloride of mercury prescribed to be taken by the mouth is much larger in France than in England, two fifths of a grain daily not being considered excessive. The rapidity and certainty with which the symptoms disappear under this treatment are almost marvelous. Taking at random one of the cases reported (the fiftieth) forty injections in six weeks sufficed to cure a syphilis which had been rebellious to the usual mercurial course for eight months. This statement that the patient was cured is the more remarkable as it comes from a man who wrote not a year since that the minimum of mercurial treatment necessary to cure was four years and upward. — *London Lancet*.

#### HOSPITAL AND ACCIDENT AMBULANCE SERVICE FOR LONDON.

WE are happy to see that a very substantial step has been taken in connection with the organization of a proposed hospital and accident ambulance service for the metropolis of London, towards the establishment of which Dr. Benjamin Howard, of New York, has been for some months entirely devoting his efforts. The London Hospital Committee having some months ago, upon the presentation of the subject to them by Dr. Howard, decided to take the initiative in this matter, the Hospital Committee, in pursuance of this plan, met yesterday to receive, from its Vice-Chairman, its first accident ambulance carriage, just built from the designs and under the directions of Dr. Howard. The ambulance having been tested in every way by the medical and surgical staff, the Hospital Committee, and

others, a resolution was proposed by the Chairman of the Hospital, and carried by the Committee and staff, stating that they highly approved of the special form of carriage devised by Dr. Howard, and conveying to him their cordial thanks for his skillful and generous services. This ambulance is in many points unlike, and apparently superior to, any in use in America; and, in its passage through the streets, as well as at the hospital, elicited enthusiastic commendation. The London Hospital Committee, in conjunction with the

National Health Association, has decided to call a meeting at an early date for a general conference of the various hospital authorities of London on the entire scheme of hospital and accident ambulance service proposed by Dr. Howard for this metropolis.

This, scheme which the *London Times* and the *Lancet* say is adapted to meet a tremendous public need, is now under the direct patronage of the Duke of Cambridge, who will preside at the coming conference. — *Brit. Med. Journal*, December 21, 1881.

# REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 28, 1882.

## THE CASE OF GUTEAU, ASSASSIN OF THE PRESIDENT OF THE UNITED STATES.

BY CHARLES F. FOLSON, M. D.

CHARLES JULIUS GUTEAU was born September 8, 1841. His paternal grandfather was a physician highly respected and of intense religious feeling. His father, a man of character and intellect, of uncommon business capacity, was a religious fanatic devoted to free-love socialistic teaching during the last thirty years of his life; he died at the age of seventy of some disease of several months' duration and attended with emaciation and delirium. By some of his family, and some of those who saw him in his relations to his delusions, this father was considered at least partially insane, but the more general opinion apparently was that he was only eccentric. Eighteen years ago he visited the Central Hospital for the Insane at Jacksonville, Illinois, to take a patient there, and he remained several days. His delusions with regard to his own intimate relations with the Deity, his attempts to cure the insane by the laying on of hands, supposing himself to be divinely commissioned to effect cures in that way, and his general demeanor, led Dr. McFarland, the medical superintendent of the asylum, to at that time consider him insane. One paternal uncle of the assassin died insane in an asylum, a second was a drunkard and finally imbecile; of one paternal aunt, who died of "consumption," and who had an insane daughter, her husband having also been insane, it was testified and denied that she was morbidly in dread of her family's going to the poorhouse; another paternal aunt, with regard to whose mental condition the testimony was contradictory, but of whom there was some evidence of insanity, had an insane son, committed to an insane asylum. Guteau's paternal grandmother died of consumption. His mother, at the time of his birth, had been confined to her bed for some time with a disease attended with marked cerebral symptoms, for which her head had been shaved, and her two children born in later life died at the ages respectively of two years and twenty months. His only sister, after her evidence in court, had an attack of *petit mal*, to which her physician said she was subject; and he also said that she had earlier in life had puerperal mania. Guteau's only brother testified:—

"My religious theory is that there are two forces in the universe,—one under Satan or the devil, and one under God or Jesus Christ; my father held to the view that there were living in the world those who were seized of the devil or Satan, and of Christ or God; he believed that these two forces were at war, one with the other, and that at present and since the fall of man Satan had, to a very great extent, dominion on the earth to possess himself of all those he could, and that he did possess himself of all those who were not absolute believers in the Lord Jesus Christ as Saviour, and who had not been saved from the power of sin by a complete union with the Lord and Saviour Jesus Christ; that all evil, all disease, all deformity, all infirmity was the result of sin or the admission of those who had a free will that they were under the dominion of Satan or the evil spirit, or of evil nature. That was my father's theological view, it was my brother's, it was mine."

Guteau's only half-sister, aged about twenty-six, has exophthalmic goitre, and of his only half-brother, about twenty-three years old, no testimony was given.

Guteau was a willful and bright child, unable for a long time to pronounce certain words ("quail" he called "pail," and "come," "ped"), and, after the death

of his mother when he was seven years old, he was left without parental care, his father having been absorbed in his business as cashier of a bank, and in the religious vagaries of the Oneida Community, a society based upon the absence of the marriage tie, upon communism in ownership of property, and a certain fanatical belief in inspiration from God as the basis of their methods of living,—perhaps rather as a cover for their impure relations of the sexes. His father treated him with great harshness and with neglect.

Guteau had no serious injury or accident other than a severe blow over the upper and posterior portion of the left side of the frontal bone, corresponding to which there remains a scar. Guteau was indisposed to manual labor, but fond of books, and especially of reading the *New York Tribune*, from which he gained a great admiration of self-made men, whose successful lives he meant to imitate. The evidence is too meagre to show whether or not, up to the age of eighteen, he differed materially in intellect from other ambitious boys. He once struck his father in anger. Soon after that time, however, he gave up his studies and plans of a liberal education, and became so absorbed in religious fanaticism as to neglect his work, and to attract the attention of his friends, who began to have fears for his sanity. His letters then changed from being simple and natural to the religious and exhorting style. It is stated that he became addicted to evil practices too common among boys, and that from other bad habits he contracted the mild form of venereal disease, so that when he gave up his collegiate studies at the age of nineteen to enter the free-love community at Oneida, it was maintained that he did so not entirely from religious motives or in obedience to his father's often-repeated wish that he should do so, but partly at least from licentiousness or the inordinate force of the sexual function so common in the congenital form of mental degeneration. While with the community he was a nervous, quick-tempered man; if anything was said to disturb him he would get angry, and would gesticulate wildly, and talk in a mysterious manner; he would sit for hours in a corner saying nothing to anybody; at other times he would be cheerful. He availed himself of the opportunity to study in the library, but showed an extraordinary self-will, vanity, restlessness of restraint, indisposition to industrious habits, and finally such boundless personal aspiration that he left Oneida. He was disgusted with his comparatively low position and mental employment, and with the coldness of the women of the community toward him. He had been there five years, during which time he had given up regular study, and imbibed communistic ideas. He even claimed inspiration (as he now claims to have had when he joined the society) when a few weeks later he attempted, in a farcical imitation of a distinguished journalist, to establish a great daily paper, called the *Theocratic Press*, which was to take the place of all the churches and provide to the whole United States religious instruction daily. At that time he was living in an attic on crackers and lemonade, without knowledge of the world, friends, or capacity, and with only nine hundred dollars in money. In a letter to his father, dated April 10, 1865, he spoke of this project as follows:—

"I came to New York in obedience to what I believed to be the call of God. With the Bible for my text book and the Holy Ghost for my schoolmaster, I can pursue my studies without interference from human dictation."

"And here it is proper to state that the Energies of my life are now, and have been for months, *pledged to God*, to do all that within me lies to extend the Sovereignty of Jesus Christ by placing at his disposal a powerful daily paper. I am persuaded that Theocratic Presses are destined, in due time to supersede to a great extent pulpit oratory. There are hundreds of Thousands of ministers in the world, but not a single daily Theocratic Press. It appears to me that there is a splendid chance for some one to do a big thing for God, for humanity, and for himself. At no time since the creation of the world have mankind been prepared for such an innovation. Instead of persons spending an hour or two, (as they now do,) *once in 7 days in religious thought*, we should present them a Theocratic daily each morning at their breakfast table, and thus introduce *God into the practical affairs of life*. The grand object of the paper would be to infuse into the public mind *true ideas of God*, of Christ, and of the Spiritual World, and to establish a *true Standard of righteousness* by inculcating the doctrine that the fear of the Lord is the beginning of wisdom.

"Do you say that the Establishment of a great daily paper is a stupendous work and only to be accomplished by extraordinary talents and Energy. Of course it is; and when I consider the vast work to be done, and my own insignificant attainments, my heart sinks within me; 'but *when I am weak*,' says Paul, '*then I am strong*;' I say boldly that I claim inspiration.

"I claim that I am in the employ of *Jesus Christ & co*, the very ablest and strongest firm in the Universe, and that what I can do is limited only by their power and purpose. I have very little confidence in the flesh; but a vast deal in the power and purpose of God; and I know that He will give me the requisite energy and ability to do my work *well*. The favor of God is vastly more important (in my view), in the pursuit of an object than any thing else.

"Whoever Edits such a paper as I intend to establish will doubtless occupy the position of Target General to the Press, Pulpit, & Bench of the civilized world; and if God intends me for that place I *fear not*; for I know that He will be 'a wall of fire round about me;' and keep me from all harm.

"To compete with the Devil you must use the *Same* agencies in propagating *truth* that he does in propagating *error*, and thereby supplant *evil by good*. I am therefore bold to confess that I should support the paper as other dailies are; ie, by subscription advertisements & the free contribution of friends of the cause.

"Perhaps the same munificence that has sustained the American Bible Society, erected magnificent Churches and kept tens of thousands of ministers in luxury, would if it could be *controlled* sustain a national chain of Daily Theocratic Presses."

His failure was a matter of course, indeed, his attempt hardly even assumed the form of definite work, and about six months after he left the Community he was eager to return, full of promises of a life of obedience to the leader, and disappointed with his utter inability to earn a livelihood by his own efforts. He had become convinced that the communists' idea of life was the correct one, that it was destined to supplant all religions, and that he was to be at the head of it. After another year there he left again, clandestinely. His threat to sue the Community for fifteen hundred dollars a year for his services while with them was followed by strong denunciatory language of their free-love life, but the suit was abandoned from want of success, fear of the results of his attack, or diversion of attention to something else. It is stated upon good authority, but not in evidence, that the intention was to claim insanity from masturbation in Guiteau if the suit was pressed.

From 1866 to 1871 Guiteau's life was rather an unsettled one. After a brief stay and second failure in New York, he spent most of his time in Chicago studying law, and trying to practice, attending religious meetings assiduously. He never had more than a small knowledge of the law, and his business consisted chiefly in collecting bad bills, which he often neglected to pay to the owners. He married an estimable lady, whom he met at the Christian Association in 1863, lived with her four years, committed adultery with a prostitute, and appeared as his own witness to secure

a divorce in 1874. Inasmuch as he acknowledges having had both syphilis and gonorrhoea, it is inferred that his life was more licentious than he admits.

After an unsuccessful trip to San Francisco, Guiteau appeared again in New York, where he failed as signally in practicing law as in Chicago. He hung about some of the offices during the political campaign of 1872, and although he had no capacity even for work of a low order, and actually did nothing of use, he expected a foreign mission in case Mr. Greeley should be elected. This idea he at once abandoned upon learning the result of the election. In 1874 one of his irregular law practices was commented upon sarcastically in the *New York Herald*, as a result of which he sued that paper for one hundred thousand dollars. He soon abandoned the suit, but has at least appeared to think, up to the present time, that he might secure a compromise to bring him in ten thousand dollars. In the same year he was thrown into jail for habitually defrauding people of their dues. After his release he showed himself sharp, persistent, and shrewd, as well as unscrupulous, in doing for a while rather a disreputable business in securing release of prisoners from jail through technicalities and errors in committal. That resource soon failed him. He was also once sent to jail in Chicago for retaining money not belonging to him.

In 1875 he conceived the idea of reviving a bankrupt Chicago paper, *The Inter-ocean* (an attempt which, later, in sensible form, proved successful), and of becoming a great editor, having previously tried to thrust his worthless services upon the editors of two leading New York papers to get experience. He tried to hire a large building for the purpose, selected an engine and two large presses, and attempted to arrange with a telegraph company in such a way as to reproduce the *New York Herald* word for word in Chicago every morning. Without experience, knowledge, money, or capacity, he offered one stranger to make him president of the United States if he would contribute two hundred thousand dollars to the project, and another to secure for him the governorship of Illinois if he would give fifty thousand dollars, — all this in apparent earnest. The project was dropped in a few weeks.

After failure in that direction he drifted around to the house of his sister, in July, 1875. Soon after arriving there he went to work in the hayfield with her sons. The weather being very hot he returned to the house after a short time complaining of the heat, seeming much exhausted, and lay down on a sofa. After he had rested awhile his sister asked him to cut some wood, and he went out for that purpose. In a few minutes she had occasion to pass where he was at work, and without provocation he raised the axe to strike her. She avoided him and ran into the house. She then set the hired man to watch him, with strict orders to keep near enough to prevent him from doing injury to any one until her husband's return from Chicago. In the mean time the family physician was consulted and examined Guiteau. The physician reported to his sister that he was undoubtedly insane, and his father had already pronounced him so. He then suddenly disappeared, taking with him his Bible, which he constantly read.

In 1876 Guiteau was again vainly trying to do some law work in an office in Chicago, where the Moody and Sankey meetings were held, and he was a constant attendant. He was appointed one of the ushers. He

became filled with zeal and soon began to look forward to doing the work of a great evangelist. He gave his entire time to religious study and devotions. In the following January he commenced his career as a lecturer.

He had written some very weak and trashy lectures about the Apostle Paul and the second coming of Christ, largely plagiarized from a book by the leader of the Oneida Community. He maintained that he was a great evangelist and went about from town to town, without money to pay his railroad fares or board bills, exhorting people to come to Christ and adopt his views of the Second Advent, now selling tracts, now preaching to empty houses, ridiculed, despised, turned out of hotels, driven off from trains, hardly knowing one day what he was to eat or where he should sleep the next, never seeking the haunts of criminals, always assuming great piety and seeming to fancy that in his wanderings he was really like Christ and the Apostle Paul, but yet without real moral principle.

He avoided the theatre, card playing, tobacco, and alcohol in all forms, seeming to genuinely despise all such habits, and to consider them wicked. He was low, mean, ill-tempered when aroused, but often mild in his demeanor, ready to borrow money, never intending to pay, and thoroughly unscrupulous about giving other people their dues or even their own money if he happened to have it. It was in evidence that he furnished up a sham-gold watch and tried to sell it as gold. He did not steal, and his life does not suggest the real criminal so much as the nuisance or fraud.

In 1879 he published in Boston, where he then was, a book of his lectures called *Truth, A Companion to the Bible*, "That many souls may find the Saviour." For this he never paid, and he failed to sell the few copies which he managed to get into his possession. There is very little in it to strike one's attention. It might, or it might not, have been the work of an insane man, certainly not that of a wholly sound mind. He speaks constantly of Christ as "that wonderful creature," says that "Heaven is a thousand times better than this sin-cursed earth." A specimen of his argument is as follows: "The theatres are sending many to hell. Do you think it harmful to go to the theatre?" "Yes, decidedly. What would you think of the dear Saviour, elbowing his way into a theatre to see a woman's leg? The drama tends down, not up. Many a man has been ruined by frequenting theatres. If I had my way, I would close every theatre in the land." "I do not like to say anything against the pulpit, as it represents many pious and able men; but I must speak the truth without fear or favor." . . . "Man is a moral agent. He can go to the right or left. He can choose good or evil. He can go to church or to a saloon, and end in heaven or hell."

While in Boston he kept attending religious meetings, frequented the rooms of the Young Men's Christian Union and made a few ridiculous failures in trying to lecture, announcing himself with the title of honorable, lawyer, and theologian, in one case putting himself in the handbills as *The Little Giant from the West*. He once said that he had challenged Colonel Ingersoll to debate but did not think that Ingersoll had courage enough to meet him. There were about fifty persons present at the lecture; the lecturer brought in a manuscript; he commenced by reading some half dozen lines and then skipping some half dozen pages; he went on without any connection

whatever; at the end of half an hour he evidently became disgusted and left the platform in a great hurry, as if angered at something. He then gave up theology because "it did not pay," as he said in a letter, written two weeks before the murder, and took up politics.

During the early summer of 1880 Giteau spent a number of weeks in the library of the State House in Boston. He was quiet and orderly, studying law and the statutes of the several States. He had several untidy habits and was finally informed that the room was not a lodging place, when he ceased coming to it. In September of the same year he acted as solicitor to one of the insurance companies in New York and brought in six applications, living most of the time, as before, by not paying his bills. With regard to that point, it appeared that he paid when he had the means of so doing, but seemed entirely oblivious of his duty to earn money. He sometimes said that he was a servant of the Lord and like Christ paid no bills. When he tried to borrow money he did so in a way to show that, so far at least, he had the methods of a very shrewd rogue.

He wrote a sharp and very weak, but not otherwise noticeable, speech of no merit at all in favor of General Grant as President, which he changed under the title of "*Garfield vs. Hancock*" after the nomination of Mr. Garfield, to whose election he appeared to really think that he had largely contributed, although he had done nothing but hang about the political headquarters and occasionally get a word from some prominent man. His speech he began to deliver only once to a small audience, but did not finish it, and yet after the election he wrote Mr. Garfield, to whom he was of course unknown, that

"We have cleaned them out just as I expected. Thank God! Very respectfully,  
CHARLES GITEAU."

He early hoped to receive an important appointment, and November 11, 1880, wrote to the Secretary of State as follows:—

HON. WILLIAM M. EVARTS:—

DEAR SIR,—I wish to ask you a question. If President Garfield appoints Mr. A to a foreign mission does that supersede President Hayes' commission for the same appointment? Do not all foreign Ministers appointed by President Hayes retire on March 4 next? Please answer me at the Fifth Avenue Hotel at your earliest convenience. I am solid for General Garfield, and may get an important appointment from him next spring.  
Yours very truly,  
CHARLES GITEAU.

During October and January he had written to President Garfield, calling attention to his services in the campaign, and soliciting an appointment on the ground that he and a wealthy lady, whom he said he meant to marry, would well represent the United States. On the 8th of March he addressed a letter to the President, calling attention to his desire to be appointed to the Paris Consulate. On the 11th of March he wrote Mr. Blaine the following letter:—

MARCH 11, 1881

SENATOR BLAINE:—

In October and January last I wrote General Garfield touching the Austrian Mission, and I think he has filed my application and is favorably inclined. Since then I have concluded to apply for the Consul General at Paris instead of the Austrian Mission, as I prefer Paris to Vienna. I spoke to the General about it and he said your indorsement would help it, as it was in your department. I think I have a just claim to your help on the strength of this speech [his speech was inclosed], which was sent to our leading editors and orators in August. It was about the first shot on the rebel war claim idea, and it was the idea that elected General Garfield.

Mr. Walker, the present Consul at Paris, was appointed

through Mr. Evarts, and I presume he has no expectation of being retained. I will talk with you about this as soon as I can get a chance. There is nothing against me. I claim to be a gentleman and a Christian.

Yours, very respectfully, CHARLES GUITEAU.

He followed up this communication by persistent personal appeals, and by writing notes and letters, urging in various ways his claims for the position. Wearied of his importunity the Secretary of State on Saturday, the 14th of May, according to the prisoner's statement in writing, said to him, "Never speak to me again on the Paris Consulship as long as you live." On the following morning he wrote to the President, informing him of Mr. Blaine's statement and saying he was satisfied that Mr. Blaine was endeavoring to ruin the State Department in the interests of his own candidacy for the Presidency in 1884, and appealing to the President direct for an immediate order for his appointment. During this time he continued to visit the Executive Mansion, and urged and insisted on an opportunity to see the President. Finally, it became necessary, in order to avoid his presumptuous intrusion, to prohibit his entrance into the White House. On the 23d of May he wrote President Garfield a letter as follows:—

(Private.)

GENERAL GARFIELD, — I have been trying to be your friend. I do not know whether you appreciate it or not, but I am moved to call your attention to the remarkable letter from Mr. Blaine, which I have just noticed. According to Mr. Farwell of Chicago, Blaine is a vindictive politician and an evil genius, and you will have no peace till you get rid of him. This letter shows that Mr. Blaine is a wicked man, and you ought to demand his immediate resignation; otherwise you and the republican party will come to grief. I will see you in the morning if I can, and talk with you. Very respectfully,

May 23. CHARLES GUITEAU.

And yet on the 21st of March he wrote to Secretary Blaine:—

"I am very glad personally that the President selected you for his Premier. . . . You are the man above all others for the place."

There was a period during this time when there existed discussions in the party in power, and there were frequent utterances of bitterness by partisans on both sides.

Without money or friends or influence of any kind, not paying his board bills, a man of utterly no consequence (and never treated as if he were), a wanderer, without a home, penniless, a man who had never really succeeded in anything in his life or gained the lasting respect of anybody, convinced that society was rotten and unjust, he wrote letter after letter to the White House, without being at all discouraged that no attention was paid to them. Indeed, he became a perfect nuisance in his persistent hanging about the State Department, and yet he wrote to the President familiar letters of advice, to which, of course, no attention was paid. A few of them are quoted:—

(Private.)

March 8, 1881. GENERAL GARFIELD, — I called to see you this v. m., but you were engaged. In October and January last I sent you a note from New York touching the Austrian Mission. Mr. Kasson, of Iowa, I understand, wishes to remain at Vienna till fall. He is a good fellow, I should not wish to disturb him in any event. What do you think of me for Consul General for Paris? I think I prefer Paris to Vienna, and, if agreeable to you, should be satisfied with the Consulship at Paris. The enclosed speech was sent to our leading orators and editors in August. Soon thereafter they opened on the Rebel war claim idea, and it was this idea that resulted in your election.

Mr. Walker, of New York, the present Consul at Paris, was appointed through Mr. Evarts, and I presume he has no expectation of being retained. The senators Blaine, Logan, and Con-

king are friendly to me, and I presume my appointment will be promptly confirmed. There is nothing against me. I claim to be a gentleman and a Christian. C. G.

(Private.)

GENERAL GARFIELD, — I understand from Colonel Hooker, of the National Committee, that I am to have a consulship. I hope it is the consulship at Paris, as that is the only one I care to take, now that Mr. Phelps has the Austrian mission. I think I have a right to press my claim for the consulship at Paris. I think General Logan and Secretary Blaine are favorable to this, and I wish you would send in my name for the consulship at Paris. Mr. Walker, the present consul, I do not think has any claim on you for the office, as the men that did the business last fall are the ones to be remembered. Senator Logan has my papers, and he said he would see you about this.

Very respectfully,

CHARLES GUITEAU.

March 26th.

(Private.)

GENERAL GARFIELD, — From your looks yesterday I judge you did not quite understand what I meant by saying "I have not called for two or three weeks." I intended to express my sympathy for you on account of the pressure that has been on you since you came into office. I think Mr. Blaine intends giving me the Paris consulship, with your and General Logan's approbation, and I am waiting for the break in the Senate. I have practiced law in New York and Chicago, and presume I am well qualified for it. I have been here since March 5, and expect to remain some little time, or until I get my commission. Very respectfully,

CHAS. GUITEAU.

April 5.

(Private.)

GENERAL GARFIELD, — I wish to say this about Mr. Robertson's nomination. Would it not be well to withdraw it on the ground that Mr. Conkling has worked himself to a white heat of opposition? It might be done quietly and gracefully, on the ground that since the nomination many merchants and others in New York had petitioned for the retention of General Merritt. It strikes me that it would be true policy to do this, as Mr. Conkling is so determined to defeat Mr. Robertson, and the chances are he may do it. It is doing great harm all around. I am very sorry you have got Conkling down on you. Had it not been for General Grant and Senator Conkling we should have lost New York. The loss of New York would have elected Hancock. Mr. Conkling feels you ought to have consulted him about the appointments in his own State, and that is the reason he is so set against Mr. Robertson; and many people think he is right. It seems to me that the only way to get out of this difficulty is to withdraw Mr. Robertson, on the ground that since his nomination the leading merchants of New York have expressed themselves as well satisfied with General Merritt, who certainly is not a "Conkling man." I am on friendly terms with Senator Conkling and the rest of our Senators, but I write this on my own account and in the spirit of a peacemaker.

I have taken the liberty of making this suggestion to Mr. Blaine, and wish you and he would give it due attention.

Very respectfully,

CHARLES GUITEAU.

April 29.

(Private.)

GENERAL GARFIELD, — I am sorry you and Senator Conkling are apart, but I stand by you on the ground that his friends Morton, James, Pearson and the rest of them have been well provided for, and Mr. Conkling ought to have been satisfied.

Very respectfully,

CHARLES GUITEAU.

May 7.

(Private.)

TO GENERAL GARFIELD, — I have got a new idea about '84. If you work your position for all its worth you be nominated and elected in '84. Your opponents will probably be General Grant and Mr. Blaine. General Grant will never be so strong again as he was just after his trip around the world. Too many people are dead set against a third term and I don't think he can be nominated much less elected again. Two national conventions have slaughtered Mr. Blaine on account of his railroad record and connections.

The republican party are afraid to run him. This leaves the way open for you. Run the Presidency on your own account. Strike out right and left. The American people like pluck, and in '84 we will put you in again. C. G.

WHITE HORSE, May 10.

P. S. — I will see you about the Paris Consulship to-morrow, unless you happen to send in my name to-day.

(Private.)

GENERAL GARFIELD, — Until Saturday I supposed Mr. Blaine was my friend in the matter of the Paris Consulship, but

from his tone Saturday I judge he is trying to run the State Department in the interest of the Blaine element in '84. You are under small obligations to Mr. Blaine. He almost defeated your election by the loss of Maine. Had it not been for Hancock's blunder on the tariff, and the decided efforts of the stalwarts, you certainly would have been defeated after the loss of Maine. You recalled Mr. Noyes for Mr. Morton, and I wish you would recall Mr. Walker for me. I am in with Mr. Morton and General Arthur and I will get them to go on my bond, General Logan and Senator Harrison and the rest of my friends will see that it is promptly confirmed. "Never speak to me again," said Mr. Blaine, Saturday, "on the Paris consulship as long as you live." Heretofore he has been my friend, but now his eye is on a "Blaine man" for the position that will help him in '84. Two national conventions have slaughtered Mr. Blaine, and he ought to see that there is no chance for him in '84. I want to get in my work for you in '84.

I am sorry Mrs. Garfield is sick, and hope she will recover soon. CHAS. GUITEAU.

May 16.

(Private.)

GENERAL GARFIELD. — I hope Mrs. Garfield is better. Monday I sent you a note about the Paris Consulship; Tuesday one about '84. The idea about '84 flashed through me like an inspiration, and I believe it will come true. Your nomination was a providence and your election a still greater providence. Had Hancock kept his mouth shut on the tariff he would have been elected probably, notwithstanding Grant and Conkling and the treachery of Kelly. Business men were afraid to trust a man in the White House who did not know "A" about the tariff, and this killed Hancock. You are fairly elected and now make the best of it. With two terms in the White House and a trip around the globe you can go into history by the side of General Grant. May I tell Mr. Blaine to prepare the order for my appointment to the Paris consulship, vice George Walker, recalled?

C. G.

WHITE HOUSE, May 13, 1881.

From the time of his arrival in Washington and until he had lost the expectation of favors to be received, and made up his mind to kill the President, — a period of nearly three months, — he was an earnest, so-called, Garfield man. He announced to the President his devotion and fealty to him. He desired constantly to impress upon the President that he was for him as against every one else. May 7th he had announced to the President that in the contest going on he stood by him.

Six weeks before the murder Guiteau "conceived the idea of removing the President;" it flashed across his mind one night when he was lying weary on his bed. He says that the idea was revolting to him and that he struggled and prayed to get rid of it, or to be assured whether it was a suggestion from the devil or an inspiration from the Deity. In the meanwhile he wrote the letter of May 23d, just quoted. He maintains that on the first of June he learned that he was acting under "Divine pressure" or "inspiration," words that he had previously used in regard to other and ordinary acts of life.

On the eighth day of June he borrowed from an acquaintance fifteen dollars, representing that he was out of money and desired the amount to pay his board bill. After procuring this loan he at once visited a store for the purpose of purchasing a weapon. He asked for a pistol of the largest calibre, one that would do the most effective work, and was shown and purchased a weapon carrying a bullet of the largest size. He carried it twenty-four days and often dogged the footsteps of the President. On the morning of the 18th of June he ascertained from publications in the newspapers that the President would go to Long Branch, and he determined to kill him at the depot. He went there fully prepared for that purpose and was deterred from its accomplishment. Returning to his room he wrote: —

WASHINGTON, Saturday Evening, June 18, 1881.

I intended to remove the President this morning at the depot as he took the cars for Long Branch, but Mrs. Garfield looked so thin and clung so tenderly to the President's arm that my heart failed me to part them, and I decided to take him alone. It will be no worse for Mrs. Garfield to part with her husband this way than by a natural death. He is liable to go at any time, any way.

C. G.

He had attended the President's church, standing in the aisle for the last half hour of the service to see the position of the President's seat, and then viewed it from the outside to learn how he could shoot him from a window behind his back. He lurked in an alley, watched in the park, and sought opportunities for the murder nearly three weeks, several times giving up his intention of shooting Mr. Garfield for reasons apparently of mere practicability. I doubt whether a murder has ever been committed more deliberately and with more careful preparation for every possible event, a statement which may also be made of a recent murder of an attendant in a Massachusetts asylum by an insane patient who has thus far escaped detection.

Early on the morning of July 2d last he made preparations for the murder. Breakfasting (for which he did not pay) at the Riggs House (a first-class hotel) he took the weapon that he had previously obtained, and going to the foot of Seventeenth Street, away from residences and beyond observation, he planted a stick in the soft mud on the river bank where the tide had gone out and deliberately practiced his aim and tested his weapon. He intended that there should be no failure in the accomplishment of the crime for which he had been preparing. Returning he took with him a small bundle of papers and went to the Baltimore and Potomac railroad depot at half-past eight o'clock A. M., an hour before the arrival of the President. After reaching the depot he went to the news-stand and left certain papers, with a letter addressed to Byron Andrews, a correspondent of the Chicago *Inter-ocean*, and a package addressed to Mr. Preston, of the *New York Herald*, and then went into the closet, carefully examined his weapon, placed it in his pocket, returned and went outside to the pavement, had his boots blacked, and then, to avoid the vengeance of the community, which he feared, engaged a carriage to take him two miles to the Congressional Cemetery, close to the jail, which he had previously examined and in which he hoped to be protected. Standing back of Mr. Garfield, he fired two shots at him with entire steadiness of aim. He then turned to leave the railway station, walking calmly to the street door. Upon being seized, after the noise of the reports, he made some not very violent remonstrance and then said that he wished to send General Sherman a letter, which proved to be a demand for his protection by the army. The evidence showed that he looked desperately in earnest but behaved with composure. He also had prepared an address to the American people claiming that he had acted for the good of the country, to make Arthur President, and to save us from another civil war. His pockets contained a large number of newspaper cuttings containing violent denunciations of the President. Just after the murder he said: —

"My getting or not the Paris Consulship had nothing whatever to do with my shooting the President; I shot him purely as a political necessity under Divine pressure; and it was only by nerving myself to the utmost that I shot him anyway. If he should recover and I should meet him again, I would not shoot him;

and now I leave the result with the Almighty. In case the President had said that I could not have the Paris Consuls, I intended to go to New York or Chicago and open a law office and let politics go. I shot the President without malice or murderous intent. I deny any legal liability in this case. . . . I had none but the best of feelings, personally, toward the President. . . . I put away all sentiment and did my duty to God and to the American people." About the 16th of June he wrote, in an address to the American people, "In the President's madness he has wrecked the once grand old Republican party and for that he dies; this is not murder, it is a political necessity." "I conceived the idea of removing the President four weeks ago. I conceived the idea myself and kept it to myself." He had said that Garfield's nomination, election, and removal were acts of God, and also "My idea is that I shall be nominated and elected as Lincoln and Garfield were,—that is, by the act of God." He explained his act of murder thus:—

"If Garfield was out of the way, thought I one night in bed, everything would go well. Things seemed to be going from bad to worse under his leadership and I foresaw another desolating war as the result of it. For two weeks I prayed over the possibility of the President's removal. The more I prayed about it and the more I looked at the political situation the more I saw the necessity of his removal. Finally, after two weeks of earnest prayer, I decided that the Deity had called me to do it and I commenced preparation for it. This was about the 1st of June. From that day to this I have never had the slightest doubt as to the Divinity of the act or the necessity for it."

After reaching the jail he had the best night's rest for many weeks. I think there can be no doubt that he fully expected to be supported by the political opponents of Mr. Garfield, and when he learned their abhorrence of his crime, he said: "What does it mean? I would have staked my life that they would defend me." He believed, I think, that he was to become a great patriot, visit Europe, be *fêted* everywhere, receive the praise of everybody, sell a revised edition of his worthless little book on the Second Coming of Christ, reach the Presidency of the United States, and die rich, happy, contented, and famous. The evidence was contradictory as to his having once said that he should imitate the assassin of President Lincoln.

When brought into court Guiteau had with him a prepared address which he was not allowed to deliver. The opening part is as follows:—

"If the Court please, I desire to address your honor at the threshold of this case. I am in the presence of this honorable court charged with maliciously and wickedly murdering one James A. Garfield. Nothing can be more absurd, because General Garfield died from malpractice. The syllogism to prove it is this: Three weeks after he was shot, his physicians held a careful examination and officially decided that he would recover. Two months after this official announcement he died. Therefore, according to his own physicians, he was not fatally shot. The doctors who mistreated him ought to bear the odium of his death, and not his assassin. They ought to be indicted for murdering James A. Garfield, and not me. But I have been indicted, and must stand my trial for the alleged homicide. General Garfield was President of the United States, and I am one of the men that made him President. His nomination was an accident; his election the result of the greatest activity on the part of the stalwarts, and his removal a special providence. General Garfield was a good man but a weak politician. Being President, he was in a position to do vast harm to the republic, and he was doing it by the unwise use of patronage, and the Lord and I took the responsibility of removing him. I certainly never should have sought to remove him on my own ac-

count. Why should I shoot him? He never harmed me. From him I expected an important office. I considered him my political and personal friend; but my duty to the Lord and the American people overcame my personal feeling, and I sought to remove him. Not being a marksman he was not fatally shot, but incompetent physicians finished the work, and they and not me are responsible for his death. Nothing but the political situation last spring justified General Garfield's removal. The break in the Republican party last spring was widening week by week, and I foresaw a civil war. My inspiration was to remove the late President at once, and thereby close the breach before it got so wide that nothing but another heart-rending and desolating war could close it. The last war cost the nation a million of men and a billion of money. The Lord wanted me to prevent a repetition of this desolation, and inspired me to execute his will. Why did he inspire me in preference to some one else? Because I had the brains and nerve probably to do the work. The Lord does not employ incompetent persons to serve him. He uses the best material he can find. No doubt there were thousands of Republicans that felt as I did about General Garfield's wrecking the Republican party last spring, and had they the conception, the nerve, the brains, and the opportunity they would have removed him. I, of all the world, was the only man who had the conception. On the trial of my case I propose to summon some of the leading politicians of the Republican and Democratic parties, also the leading New York and Washington editors, to show the political situation and the perils which surrounded the Republicans last spring. I propose to go into this branch of my defense extensively. Another reason the Lord inspired me to remove the President in preference to some one else is because he wished to circulate my theological work, *The Truth*. This book was written to save souls and not for money, and the Lord in circulating the book is after souls. By it he preaches the gospel and prepares the world for their judgment, which to some people, and with reason, is not far distant. I have been delayed in getting out a new edition of this book, which will include a graphic narrative of my life, but I expect that it will be issued shortly. More than one hundred witnesses have been summoned by the prosecution. Two thirds of them I know nothing about, and the Court, I presume, will decide that they are irrelevant. The issue here is, 'Who fired that shot; the Deity or me?'"

He appealed to prominent lawyers for help in conducting his case and to the American people for money, on the ground that his cause was as worthy as that of the widow whose husband he had murdered, and for whom there had been a liberal subscription. He angrily protested against the lawyer assigned him by the court, reviled the other counsel, his brother-in-law, and insulted the prosecution to the last degree.

I examined Guiteau in jail a week before the trial. I did not find any positive physical evidence of brain disease. The asymmetry of the head, shown in the photograph, the slightly exaggerated arching of the palate and protrusion of the upper incisor teeth were worth noticing. In connection with other symptoms, and especially with the strong hereditary predisposition to degenerative disease, they were of some slight value as corroborative evidence of insanity. His mental state seemed to me clearly one of weakness, due, possibly, to some very early, if not congenital, form of insanity, or to the dementia produced by disease, mild if chronic, organic if acute, possibly what some alienists would call the insane temperament or partial (moral) imbecility. There was no incoherence, but the want of connection in thought was very striking. The weakness of judgment, reason, and reflection was as striking as the quickness of perception and, in matters interesting him, readiness of memory. When in the least opposed his excitement was simply maniacal, but on indifferent subjects he conversed calmly and amiably. He insisted that he was not insane, and never had been so. His whole line of defense was to be, in his mind, that the doctors and not he killed the President, and that the political situation justified the assassination,—a point which he meant to establish by

the testimony of the leading politicians and newspaper editors of both parties; and yet beyond the mere suggestion he had no definite plan, and was diverted from one subject to another like a child or a general paralytic. He did not know that I was a physician; he seemed to pay very little attention to me at first, and went on talking with his counsel as if I were not there. He appeared to me to consider himself a great man, the friend and equal of the first, the maker of a President, the savior of his country, an evangelist who meant to save the world by a worthless book, a politician whose miserable little speech, which he delivered only once to a couple of dozen negroes, did much to elect Mr. Garfield, and insured him the right to one of the highest offices of the land, a low, syphilitic lover who was to marry a wealthy and cultivated lady (to him unknown) simply by the asking, a hero who was going to Europe to be *fêted* as was General Grant, and to live a long life, rich and happy. I certainly had never before seen such a grotesque contrast between lofty delusion and low reality except in cases of general paralysis of the insane.

My opinion, given after thinking over the interview for a few days, and which I said that I might modify after further knowledge of the case, was as follows:—

(1.) When Guiteau shot the President it was under the influence of a delusion consistent with previous manifestations of insanity.

(2.) His shooting the President was, to a certain extent, the logical result of bad training, character somewhat unscrupulous, enormous self-conceit, self-will, disappointment in not getting office, cowardice, extreme political partisanship, delusions or deceit regarding religion, desperation of poverty, expectation of personal gain, love of notoriety, and hope of praise from the "stalwarts."

(3.) There is a strong hereditary predisposition to insanity in his case.

(4.) He supposed that he should escape punishment.

(5.) Certainty of punishment would have restrained him from the act.

(6.) He could and did on several occasions exercise self-control regarding his delusions about shooting the President,—perhaps knowing that he should have other chances.

(7.) He knew that his act was wrong in general, but believed that the good to his political party and to the country counterbalanced the wrong, and made the deed heroic. How far he acted under the delusion that God directed his deed I am not sure, with my present evidence.

(8.) Crime and insanity are so mixed up in his case, that I should want more evidence before deciding what my views would be as to his punishment.

(9.) His punishment might deter others of his class from similar deeds, but his hanging under circumstances involving publicity as to details would probably incite insane persons of another type to murder.

(10.) My present impression is that he should not be hanged, provided he can be sent to an asylum for the criminal insane, a prison, or a jail for life.

One of the senators from Illinois testified that about the 12th or 15th of March Guiteau called on him in Washington. He said:—

"He was rather peculiarly clad for the season, there being snow on the street at the time; he had on his feet a pair of sandals or rubbers, or something of that kind; he had no stockings; he wore a light pair of pantaloons and a common, ordinary coat; a day or two afterward he came again to my room

uninvited; he still insisted on my signing his recommendation, reiterating the same statement as before, of his having a promise of the place if I would recommend him; I again declined. I had in the mean time, out of curiosity, read his speech; he was a little more excited at the second interview than at the first; the second was a very short interview, for I tried to dispose of the matter as quickly as possible. I thought there was some derangement of his mental organization, but to what extent I could not say; when I went down to breakfast that morning, I saw him at the table as a boarder; I called the landlady, and asked her if she knew that gentleman; she mentioned his name, and said he had told her that he was a constituent of mine. I said, 'I do not think that he is a proper person to have in your boarding-house,' she asked why; I said, 'I think he is a little off in his head,' or some language of that kind; she asked me what I meant, and I said I thought he was kind of crazy, and that she had better not have him in her boarding-house."

Guiteau's conduct in court, where I observed him for eleven days, was consistent with what I had seen in the jail; angry denunciation of his counsel for not adopting his theory of the defense, such boundless egotism and overweening conceit that he constantly even told untruths to make himself appear a man of brains, rapid changes from maniacal excitement to silly satisfaction, enormous self-will and determination without definite plan, a wavering, weak mind full of suggestions but without resource or ability to follow up his ideas, quick perception, acute memory, intense self-satisfaction, rudely brutality and lewdness, a rather exceptional degree of acuteness, and withal an evident wish and apparent expectation of being acquitted. The trial was manifestly the great pleasure of his life. When he had an opportunity to declaim to the court from his "Oration on Paul the Apostle" he was evidently lost to everything else in beaming satisfaction and joy. At last, he was the centre of observation and he reveled in it to the utmost, irrepressible, voluble, coarse, vulgar, and yet always speaking of himself as "high-toned," allowing that he had been thought "cranky" all his life, one moment grinning with pleasure, the next convulsed with passion, and constantly injuring his own cause by calling his best witnesses liars, his brother a defaulter, and his counsel a jackass. He certainly was, as he said, "dead in earnest." His cross-examination showed an amount of readiness in reply, quick wit, and "dead earnestness," that I certainly had never seen before. If he had been shamming, it does not seem to me possible that he could have avoided tripping up not only once but often.

He assumed various theories of his own insanity at the time of the murder (Divine pressure, inspiration, Abrahamian insanity, transitory mania), and cited cases of persons who had escaped punishment on that defense, — a subject with which his law studies had made him more or less familiar. He insulted the negroes one day and apologized the next, there being one negro on the jury; and he constantly appeared to be trying various pettifoggery devices to help his cause. He persistently denied facts to his disadvantage in his earlier shameful life, wandered off into advice to the Government to suppress Mormonism, or to President Arthur to discharge this officer and that, and was once so excited as to strike one of the officers of the court for simply hurrying him to his van.

When he heard that the jury had convicted him, he took the matter most calmly at first and then screamed out, "Vengeance is mine," saith the Lord, "I will repay! Beware, ye Americans, how you treat me, lest his wrath be kindled and you go down in blood and desolation." Having read of a severe railroad accident, he said that he would rather be hanged than die

such a suffering death as that. When told that some one had offered \$1000 for his body to dissect, he coolly said, "Perhaps some one will give \$2000." While awaiting his sentence Guiteau was thoroughly unmoved, and corrected in a paper the error in statement that he was selling his autographs for \$9 per hundred instead of per dozen. After Judge Cox had pronounced sentence of death he broke out, "May God have mercy on *your* soul! you need it more than I do. I am God's man. The act I did was commanded by him; and He will take care of it and of me. Nothing good has come of it. God Almighty will curse you all, from the judge down to the humblest juror. I am going to glory, but you will go below. The devil is waiting for you; and for that miserable scoundrel (the prosecuting attorney) he is preparing a permanent job below. I may not have to go for some time. I may be President yet. But, if I am hanged the nation will roll in blood." He then became calm. At the jail he insisted that he was to have a new trial and perhaps still become President. He was vaccinated at his own request to escape infection through letters sent to him.

In attempting to describe Guiteau's mental state at the time of the assassination, one is at once met with many difficulties. He had led such a vagabond life that his few friends knew little about him and the community at large was so clamorous for him to be hanged that it was impossible to get anything like full evidence. He was tried, too, four months and a half after the murder. The prisoner, although "dead in earnest" in his delusions, was still a special pleader for his own neck's safety, and was either extremely forgetful in some matters or what seems to me more probable, exceedingly untruthful. It was therefore quite impossible to get at the whole truth, or to satisfactorily sift the contradictory testimony that was offered.

With regard to his "inspiration," it evidently was an afterthought to his conception of the murder, and, as on former occasions of his life, it was the expression of the deep conviction of a weak-brained man that the Deity approved his plans. His "pressure" to kill the President, too, was perhaps not unlike the "constant pressure to write" for which he wrote his father, November 11, 1867, that he had the preposterous notion of joining the editorial staff of the *New York Independent*. His idea of special Divine protection, that the Lord interposed to save his life, when he jumped off a railroad train to avoid arrest for non-payment of fare, when there was a collision of steamers with him on one, when he shot the President in a crowd, when he was fired at on the way from the court-house to the jail and also in the jail, is, whether genuine or not, perhaps not inconsistent with bodily fear, and, like his inspiration and Divine pressure, was intensified by reason of his mental condition. He seemed to me to honestly consider himself "a servant of the Lord." He said in his lecture entitled "*Some Reasons why many Persons are going down to Perdition, including a Reply to Attacks on the Bible*," that he "knew Moody ten years ago when he was the laughing stock of Chicago. His zeal was so great for the Master that he used to go up to strangers and say 'Do you love the Lord?' 'Are you for Jesus?'" Guiteau used similar phrases in a similar way. How far that and his vagabond evangelist work were imitations of Moody, with hopes of his success, I cannot say.

The question exists in my mind whether there have

not been in Guiteau's life several attacks similar to subacute mania, each in turn leaving him more demented: *first*, when he excited the fears of his friends, at the age of eighteen, by giving up his studies, and becoming absorbed in a deep religious excitement; *second*, when he attempted the theocratic press; *third*, in the Greeley campaign; *fourth*, when engaged in his suit with the *New York Herald*; *fifth*, during the *Inter-ocean* project; *sixth*, when he raised an axe against his sister; *seventh*, at the time of his wanderings as an evangelist; *eighth*, when he expected the Austrian mission or the Paris consulship, and ending with the assassination or soon after. It was coincident with these periods of excitement—for they certainly differed from the quiet state in which he often was for months at a time—that he persecuted women with absurd plans of marriage.

The evidence, although not entirely satisfactory, seems to me to point to such attacks of mild mania resulting in considerable dementia, or to periods of maniacal excitement so common in the congenital or degenerative types of insanity or partial imbecility. In the latter case maniacal outbursts are apt to be mistaken for wickedness, because they are often, if not generally, associated with a directness of cause and effect similar to that observed in people who are simply bad.

If Guiteau has chronic subacute mania of a recurrent or paroxysmal type, it seems to me that his mental condition at the time of the trial indicated responsibility. At the time of the murder he had the extraordinary delusion that the political opponents of General Garfield, and finally the country, would approve his act, and make him a hero. How far he was incoherent, if at all, in ideas at that time, and to what extent he was suffering from maniacal excitement, are facts which, unfortunately, have not been observed by competent persons, and will never be known. It may be said that nearly every great crime is committed under the influence of some delusion, as in the case of Orsini, for instance, who tried to kill Louis Napoleon because he thought that his subtle influence was prejudicing the English nation against Italy. That is to a certain extent true, and each man has his own view of the difference between an insane delusion and a false belief consistent with sanity. It is simply a matter of degree.

If Guiteau's type of insanity is congenital or developed by the blow on his head, or at puberty, or through masturbation, there is certainly enough in his family history to make such a result quite possible. This form of insanity, although comparatively rare and often confounded with depravity, is recognized by the leading authorities on mental disease as primary and secondary moral insanity, affective insanity, impulsive insanity, *folie raisonnante*, *moralisches Irresein*, *impulsives Irresein*, *primäre Verrücktheit*, *psychische Entartung*, *originäre Verschrobenheit*, *moralische Verknümmung*. The legal responsibility in all these cases is a very obscure matter. The medical expert has simply to state the condition of moral perversion and mental unsteadiness, and the imperative nature of the conceptions of such minds, together with such a degree of intellectual capacity that it would not strike the ordinary observer as being defective or diseased, and society must deal with them as it chooses.

The best qualified of Guiteau's acquaintances to give an opinion states that his manner has entirely changed

since last Spring, that he has become more irritable, more emotional, much more exalted, and a very much more rapid talker; that he seems in expression and in act an entirely different man. He sees a new expression in the eyes, but is not sure whether the prominence of the right eyeball and slight deviation of the axis of one eye are natural or not. It was testified that before the murder his condition was one of great exaltation. There might be some ataxia or only the unsteadiness of legs arising from confinement. Upon striking the patellar tendon, the foot of each leg jerks quickly, describing an arc of about twelve inches. The tongue is flabby, and local fibrillar twitches are observed, first in one part of it, then in another. In rapid speech the articulation seems without conspicuous fault, which is certainly not the case when words are spoken slowly. The handwriting had not apparently become unsteady. These symptoms, associated with such expansive ideas and mental instability, are suggestive of an early stage of general paralysis of the insane, but do not prove it to my mind. I am by no means sure that it is not like the case reported by Christian a year ago, in the *Annales Médico-Psychologiques*, of an imbecile who had an attack of maniacal excitement at the age of thirty-one and general paralysis at about fifty, or one of those where, as Morel says, the incubation period of general paralysis of the insane is the whole previous lifetime. Guiteau ate enormously, slept well, and was badly nourished.

I have tried to select from the immense mass of evidence facts which state the whole case as impartially as possible. Dr. Godding, the medical superintendent of the Government Hospital at Washington, says:—

"In a case of as grave importance as this I would not express an opinion until I was in full relation with all the facts in the case. A man's impression is very different from his opinion. An expert's opinion should only be declared after a careful consideration of all the facts produced in evidence and a careful study of the prisoner." . . . "There is a very grave difference between medical insanity and legal irresponsibility, and on that difference this case hinges." . . . "I am sorry to see the experts classed on one side or the other. I hope the golden age is not far distant when the medical expert—all experts in fact—will simply appear as friends of the court."

Guiteau has been observed chiefly while on trial for his life and at a decided disadvantage. Even if he were shamming, as I think he was to a certain extent, that fact is as characteristic of the insane as of the sane. His whole conduct illustrates the annoyances which medical officers and attendants in insane asylums are daily compelled to bear. He seems to me to belong to that class of insane criminals who do least harm to society, after their crime, by being secluded for life in a criminal lunatic asylum, without trial, if that is practicable in our country. As the case stands, he has impressed the criminal classes and the country at large as being an unscrupulous, dangerous villain, with a badly arranged mind, feigning insanity to save his neck. The verdict of the jury has met with almost universal approval, and many of the insane in asylums, who feel that their own safety depends upon the maintenance of a high standard of responsibility there, agree with the jury. Others think otherwise: the Pöcasset murderer, for instance, says that the protection of society would be just as much influenced by one's walking out and stepping on an ant as by hanging Guiteau.

# A CASE OF LISTERIAN OVARIOTOMY IN WHICH THE BLADDER WAS FREELY LAID OPEN; UNINTERRUPTED RECOVERY.<sup>1</sup>

BY JOHN HOWANS, M. D.

IN the London *Lancet* for September 17, 1881, Dr. Bantock reports a case of ovariectomy in which the bladder was opened. In the New York *Medical Record* for October 15, 1881, is an abstract of a paper read by Dr. T. G. Thomas before the American Gynecological Society, entitled *Expansion of the Bladder over the Surface of Abdominal Tumors and its Attachment to Them or to the Abdominal Walls as a Complication of Laparotomy*. In the *Medical Times and Gazette* for November 28, 1868, Dr. Richard Neale, of London, reports an exploratory incision in a case of ovarian tumor and a singular position of the bladder, and Dr. G. Eustache, of Lille, reports in the *Journal des Sciences Médicales de Lille*,<sup>2</sup> a wound of the bladder in ovariectomy. In addition to these cases Dr. Thomas mentions six others.<sup>3</sup> The favorable result in the case I am about to report may be of service in encouraging the general surgeon to resort to an early abdominal section in intra-peritoneal traumatic injuries to the bladder likely to be followed by effusion of urine and peritonitis.

The patient upon whom I operated October 5, 1881, was a widow forty-five years old; she had never been pregnant, had never been attacked with peritonitis, and there seemed to be no adhesions. I made an incision about three inches long between the umbilicus and pubes and, after dividing the linea alba, came to a thick, muscular layer such as I never had seen during an ovariectomy. It was a pale red muscular tissue apparently more than a quarter of an inch thick. Without a thought that it might be the muscular wall of the bladder, but in order to get above it whatever it was, I cut up higher towards the umbilicus and struck the same tissue behind the rectus muscle but outside the peritonæum; I then extended my incision to the umbilicus and made a short transverse incision across this muscular mass, passed a director beneath it, and divided it longitudinally. I then found I had opened the peritonæum at the upper angle of the wound and had exposed the cyst. On looking at the incision which I had made on the director, I found that the bladder had been wounded, a piece about the size of my thumb-nail had been cut off from the elongated fundus, and the viscous had been split through both its anterior and posterior walls for an extent of about two inches. I extracted the cyst, which was a non-adherent dermoid, weighing twenty-two pounds. I then examined the opened bladder. It contained no urine, there was a clean cut through both its walls and a detached piece adherent to the peritonæum. I regarded the case as one of anatomical peculiarity in which the bladder was of unusual size and shape, not contracting under the pubes when empty, but remaining elongated, or else that this was a persistence of the urachus to a much greater extent than is usually found. I had to deal then with an intra and extra peritoneal wound of the bladder. It seemed to me that if a hole in the floor of the bladder communicating with the vagina could be easily closed by the ordinary operation for vesico-vaginal fistula, this clean

<sup>1</sup> Read before the Suffolk District Medical Society, Jan. 7, 1882.

<sup>2</sup> British Medical Journal, November 1, 1879.

<sup>3</sup> For a perusal of Dr. Thomas's paper I am indebted to Dr. J. R. Chadwick, the Secretary of the American Gynecological Society.

antiseptic wound in the *roof* of the bladder, if carefully sewed up, should be much more certain to unite and do well. There was every facility for operating at ease, just as if you were seated at a table sewing up a bag. I hesitated whether to try to stitch on the detached piece, but as it was firmly adherent to the peritoneum and had retracted upwards I thought that it would be impossible to stitch it on neatly, and that its union might jeopardize the successful closure of the wound in the bladder; at the same time if I left it I feared it might retard or prevent the union of the abdominal wound because of its mucous surface which might not become united to any adjacent tissue. The perforation of the bladder had been from above downwards and if I should pass my stitches from side to side there would remain an angle at the fundus (where the piece had been cut out) to be brought together, and the lower line of union would be dependent, consequently I passed a continuous suture of carbolized silk, moderately fine, from the right side of the bladder to the left, including only the muscular coat, and tucked in the mucous coat whenever it protruded. The result was a crescent shape to the upper extremity of the bladder with a horn on each side. I tied the two ends of the suture together and then passed a stitch through the lower angle of the peritoneum beneath the bladder, so that if the urine ran out it could not enter the peritoneal cavity. I then closed the abdominal wound as usual and put a small drainage tube in the lower angle. Before placing the patient in bed I passed a catheter and got bloody urine. A Sims' self-retaining catheter was placed in the bladder. For a few days the urine contained a few small clots of dark blood. A little warm carbolized water was injected into the bladder twice a day for three days. The catheter was removed from the bladder on the tenth day and the stitches and drainage tube were taken out of the abdominal wound at the same time. The incision was thoroughly united by the first intention and no urine had been discharged through the drainage tube. The temperature never rose above 99° F., and there never was the least shock. At the end of three weeks she went home. Dr. Bantock, in reporting his case, states that "there was great difficulty in getting through the parietes owing to the excessive vascularity and thickness of the tissues, every cut of the knife appearing to open a fresh vessel, especially at the lower angle of the wound." . . . I therefore went on with the upper half and then succeeded in getting through the peritoneum." Later on he says, "There was still some bleeding going on and in my search for the vessels I observed a peculiar rounded opening with a smooth interior. This I found to be an opening into the bladder capable of admitting my finger, with which I satisfied myself that it was really the bladder. I had already noticed a clear fluid at the lower angle of the wound which I took to be water that had dropped from my hands and collected from the spray, but was then convinced was urine."

"The opening into the bladder was now closed by a continuous suture of silk-worm gut, which did not include the mucous membrane." The patient left the hospital at the end of five weeks for a convalescent home entirely well. Dr. J. R. Chadwick, the accomplished secretary of the American Gynecological Society, has furnished me with a printed copy of the proceedings of the Society containing Dr. Thomas's paper

mentioned above. After alluding to the fact that notwithstanding the amount of careful study and prolonged investigation for the perfection of ovariectomy there were even yet special points which made their appearance, and which thus far had almost entirely escaped attention, Dr. Thomas describes at length the special complication indicated by the title of his paper and goes on to say that a "search into the history of the subject furnishes us with seven cases of this character in all of which a fatal issue has been the consequence of the adhesion, either from direct injury done to the bladder, the surgeon not recognizing the nature of the complication, or from failure to remove the tumor on account of its existence." I should like to do justice to Dr. Thomas's able and instructive paper by quoting it at length, but space will not allow me to do so. Any one, however, can read an abridgment of it in the *Medical Record* for October 15, 1881, and the complete paper in the Transactions of the American Gynecological Society soon to be published.

Finding a peculiar appearance of the tumor in the line of incision, and becoming convinced that he had to deal with a case of extensive vesical adhesion, and being unable to determine the points at which the bladder was attached to the tumor, he made an incision through its anterior wall, passed in his finger and determined the outline of the bladder. The bladder was then separated from the tumor and the latter removed. He concluded the operation after having sewed up the upper half of the incision by passing a "needle through the abdominal wall, then through one vesical wall, then through the other, and lastly through the opposite abdominal wall, and so continued to do until the whole opening in the bladder was traversed by sutures." A Sims' catheter was kept in the bladder, and at the end of three months the patient went home perfectly well.

In the discussion which followed, Dr. Kimball stated that in two cases of fibro-cystic tumor of the uterine, in which he had tied the pedicle without implicating the bladder, urine had escaped from the abdominal wound in both cases and a fatal result had followed. In another case described to him by another surgeon two holes in the bladder had been closed with silver sutures and recovery had taken place.

Dr. Noeggerath had had a fatal case in an uncompleted operation, but his remarks would lead the reader to infer that it was the severity of the disease and the impossibility of completing the operation that caused the fatal result and not the subsequent effect of injury to the bladder. Dr. Engelmann had had two cases of abdominal section in which the bladder had been spread out over the tumor.

Dr. Goodell reported another case in which the wound of the bladder was closed with catgut ligatures. The case was fatal. In Dr. Neale's case (1867) the report is as follows: "On dissecting down, layer by layer to the tumor, a very puzzling state of things presented itself. After opening the peritoneum it appeared as though there was still another layer of altered serous membrane covering the tumor; the finger introduced met with universal adhesions. After ineffectually trying to separate the adhesions the wound was closed. The next day no urine came through the catheter, but flowed out through the lower angle of the wound. On the twenty-seventh day all the urine had passed through the abdominal wound, this was reopened for several inches and the thick everted edges of the

wounded bladder were pared and brought together with fine wire sutures, and then the external incision was closed with stronger sutures." The patient entirely recovered from the operation and died suddenly six months later. At the autopsy the bladder was found to be converted into a tube eight inches in length by one to one and a half inches in diameter. After briefly describing the tumor Dr. Neale says "The interest in the case chiefly lies in: (1.) The unusual position of the bladder. (2.) The perfect recovery of that organ after the extensive wound. (3.) The great benefit of the exploration upon the general health and growth of the tumor for a time. (4.) The great advantage of carbolic acid dressings. (5.) The fact that, on account of the universal adhesions, no urine was effused into the peritoneal cavity. In Dr. Eustache's case the bladder was wounded and was sewn up with three catgut sutures including the mucous membrane. On the second day urine was passed freely and without pain per urethram. Perfect recovery followed. Here are nine cases in which the bladder had been wounded during abdominal section, with five recoveries and four deaths. In four of these cases the bladder wound was sewn up and replaced in the abdomen. The sewing material in two of these cases was silk, in one silver wire, and in one catgut. In one case the stitches passed through the abdominal parietes and the walls of the bladder. It should be noted that in all the fatal cases<sup>1</sup> reported by Dr. Thomas all the patients died within thirty hours of the operation, except the case related by Dr. Neale, which seems in my opinion to have recovered, i. e., it is the severity of the operation and the other complications that bring about a fatal result and not the wounding of the bladder. Indeed, the latter seems to heal readily as a rule if cleanly cut and neatly sewed up. The question of the best treatment for a bladder wounded during ovariectomy cannot be set down as invariable. Each case will probably have peculiarities necessitating appropriate methods. But the main facts to be learned are: first, that the ovariectomist must be on the lookout for the bladder in making his incision, and, second, he may feel encouraged that nature will heal the wound if it is carefully sewn up. Of course, as the bladder is a distensible organ, and is necessarily so, a method of union which will leave it in its normal distensible condition is better than one in which the viscous is tied to undistensible structures, but sometimes, as in Dr. Thomas's case, it is unsafe to trust to primary union of an unsupported bladder, and he very wisely avoided the risk of urinary infiltration by uniting the wound as he did.<sup>2</sup>

### A CASE OF OSTEOTOMY.<sup>3</sup>

BY A. T. CABOT, M. D.

A SPECIMEN from a recent osteotomy of the femur must ever be a rarity; for recovery from this operation is the rule almost without exception, and intercurrent

<sup>1</sup> Vide Transactions of the American Gynecological Society for 1881.

<sup>2</sup> The best article on the treatment of intra-peritoneal wounds of the bladder that I have seen is one by Dr. E. Vincent, Surgeon of the Charity Hospital of Lyons. It is entitled "Plaies pénétrantes intrapéritonéales de la Vessie," and is published in the consecutive numbers of the *Revue de Chirurgie* for June and July, 1881. Dr. Vincent quotes freely from the excellent article by Dr. Bartels, Die Trauman der Harnblase, von Dr. Max Bartels, in Berlin. Arch. für klin. Chirurgie von Laugenbeck. Bd. XII, pages 513, 715, 1878.

<sup>3</sup> Read before the Surgical Section of the Suffolk District Medical Society, January 7, 1882.

maladies seldom supply the chance to study the results of one of these operations till after the displaced parts are so changed by absorption and by the deposition of new tissue that conclusions as to the exact nature of the original injury are impossible. I have, therefore, thought it worth while to publish a wood-cut of such a specimen, which, being cut from a photograph upon the block, reproduces the appearances very exactly.

The history of the case is as follows:—

Mary T., a colored child six years of age, was sent to me by her parents in consequence of extreme rachitic deformity of the legs. The father was healthy; the mother had suffered from hip disease in her youth, and had recovered with ankylosis and apparently considerable shortening. The older brother of my patient was a well-formed boy of nine or ten. A younger brother, three years of age, however, had had an extreme degree of curvature of the tibia, which had been corrected by osteodolasis. This was done at so early an age because a marked compensatory deformity of the ankles was developing.

Mary's condition when I examined her was the following: Both femora were considerably bowed outwards and forwards. The left knee was in a marked condition of genu valgum, and the right knee showed a slight degree of the same deformity. Both tibiae were bent sharply forward at the junction of the middle and lower thirds.

The child entered the Children's Hospital in July, 1881, and the lower limbs were straightened by osteodolasis, as will be reported at some future time in a series of these operations. During her stay in the hospital she had whooping-cough mildly. When the legs were strong again the child, though in excellent health apparently, was sent into the country for a few weeks, to avoid a too long continuous stay in the hospital.

In October she reëntered with us, and on October 13th was operated upon for the correction of the deformity of the left knee. I employed Macewen's method in this operation.

The knife was entered on the inner aspect of the knee, about one inch above the articulation. It was thrust immediately down to the bone, and an incision one inch in length was made upwards in the axis of the femur through the whole thickness of the soft parts. Before withdrawing the scalpel a chisel 1.5 cm. in diameter was introduced along it, turned at right angles across the axis of the bone, and the shaft of the femur was divided through about three fourths of its diameter. As the bone at the point operated upon was somewhat broader than the chisel, this had to be withdrawn once or twice and reintroduced before the whole width of the bone was severed. Care was taken, however, never to drive the chisel across the whole transverse diameter of the bone, in order to avoid injury of the periosteum on the outside.

The femur being now three quarters divided, the leg was seized and straightened, which was accomplished with but little exercise of force.

There was almost no bleeding from the wound, which was done up carefully with carbolic gauze, the whole operation having been conducted under spray, and with all antiseptic precautions.

Lastly, the leg was bandaged from the toes to the upper part of the thigh with a plaster bandage, and carefully held in good position till this had set and was firm.

No constitutional disturbance followed this operation. The temperature never rose to 100° F., and after the second day continued perfectly normal. The dressing did not soak through, and was consequently left in place.

November 7th. Three and a half weeks after the operation the plaster bandage and Lister dressing were removed. The wound had wholly healed, and the bone was apparently firmly united, with no perceptible callus. The child was still kept in bed, however, in the fear that the leg was not yet strong enough to bear her weight.

November 13th. She became feverish, and soon developed marked typhoid symptoms,—headache, epistaxis, diarrhoea, tympanites, with a characteristic temperature curve. In spite of every care her strength steadily failed, and she died November 22d, five and a half weeks after the osteotomy. Figure 1 is taken

FIG. 1.

FIG. 2.

from a drawing made in May, Figure 2 from one after death.

A complete autopsy was not allowed, but I was permitted to examine the left leg, and obtained the specimen from which the wood-cut is taken.

FIG. 3.

In this figure (Figure 3) the inner side of the bone upon which the chisel was entered is to the left. At *c* we have the line of the epiphysis. Three fourths of an inch above this is the line of division. A glance at

this shows that while on the outer side of the bone the line of the shaft is pretty well preserved, on the inner side a considerable displacement has occurred. The compact wall of the shaft has been driven down into the cancellated tissue to the point *a*. The tissue in the middle of the shaft, on the other hand, was less resistant than the more densely cancellated tissue below, so that here the centre of the lower fragment is impacted into the upper. A very firm locking of the fragments is the consequence, and this no doubt greatly facilitated the rapid recovery. That there has been but slight reaction in the parts about is shown by the absence of callus. The only true callus formation is seen at *b*, where a little new bone has been thrown out over the free end of the lower fragment; besides this there is only a very thin layer of new bone under the periosteum on the outer side.

The course of this case and the post-mortem appearances furnish strong evidence in favor of this method of operating, which leaves the outer side of the bone intact. If the bone were chiseled from the outer side, when it was straightened, a wedge-shaped gap would be left between the fragments, which would have to be filled with new bone before the healing would be complete. This would, of course, require more time than a method by which the fragments were closely applied to each other and really locked together. This point has been very clearly argued by Macewen in his excellent monograph on the subject.

Another advantage in this method is the immediate stoppage of the hemorrhage. Most of the bleeding comes from the cut surfaces of the bone. This is stopped when these surfaces are forced together, but allowed to take place when they are held apart. The limited amount of hemorrhage in this case allowed the wound to entirely heal under the first dressing, thus avoiding the necessity of entering a window in the plaster or disturbing the wounded parts by a change of dressings.

## REPORT ON PROGRESS IN THE TREATMENT OF THORACIC DISEASES.

BY F. L. KNIGHT, M. D.

### DIGITALIS IN DISEASES OF THE CHEST.

Dr. H. C. Wood made some very valuable and timely remarks on the use of this drug at a meeting of the Philadelphia County Medical Society.<sup>1</sup> In opening the discussion he referred to the current views in regard to the action of digitalis upon the nervous apparatus of the heart, and claimed for it a peculiar effect upon the heart-muscle.

This influence, which had been fully demonstrated by physiological experiment, and sustained by chemical observation, renders digitalis particularly serviceable in the condition of heart disease in which the increased work required of the heart is greater than the increase of the power, without regard to the particular valve which may be affected. It improves the nutrition of the heart by regulating its contractions and lengthening the diastolic interval, doing away with the rapid, imperfect contractions which interfere with the blood supply of the cardiac muscle. In such cases the nutrition of the heart suffers because it is necessary to have lateral distension of the aorta in order to fill the arteries in the muscular tissue. A little digitalis studies

<sup>1</sup> Philadelphia Medical Times, vol. xi., No. 355.

the heart and therefore improves its condition and retards degeneration.

In chronic valve trouble of the heart digitalis is serviceable, and sometimes must be given in large doses. A half-drachm dose of the tincture apparently saved from impending death two cases of advanced heart trouble coming under the speaker's observation; they afterwards got well enough to attend to their business. It enables the heart to gather up its strength, and keeps it going until the last. By the surgeon digitalis is often used improperly. Thus it is not rarely given in aneurism, where the great danger is from increased lateral pressure. In one case coming under his observation digitalis caused the rupture of an internal aneurism at the hospital. The patient had been brought in without any diagnosis, and no one had suspected aneurism.

In acute diseases with failing heart digitalis might be employed; such a condition may occur in asthenic or in the advanced stages of sthenic pneumonia. In the early stage of sthenic pneumonia it is improper to give it. Such a medicine as *veratrum viride*, which produces vaso-motor paralysis, is indicated, "so as to bleed a man into his own tumors." Blood is drawn to the lungs because there is a local vaso-motor palsy; produce a general vaso-motor palsy, and the local attraction ceases. When the lung is consolidated throughout a large extent the heart is overworked; by and by it begins to fail, the pulse gets rapid and feeble; now digitalis comes into play. It will save life in such a condition, when the patient without it must die. Take the case of a drinking man seen a few days since, suffering with pneumonia, pulse 150 to 160, respirations 60 to the minute, delirium persisting for two or three weeks, expectoration of pure blood, etc. This man was given ten minims of tincture of digitalis every two hours, day and night, until the pulse fell to 60, — when the digitalis was stopped, and resumed as the pulse went up. By the aid of milk and whiskey the patient was saved.

Two points in conclusion: (1) in regard to the cumulative action, (2) in regard to the slow cause of the action of digitalis. The remedy acts slowly in producing its effects, and its effects are very permanent when they do appear. Some agents act more quickly than others; digitalis acts slowly and cumulatively, not only because of its special influence upon the heart, but because it only comes very slowly in contact with the heart structure, since it osmotes slowly into and out of the body. Where it fails to act upon the kidneys it is more apt to act cumulatively upon the heart. The practical point is this: watch the kidneys when giving large doses of digitalis; if water is not passed freely then cumulative action will be apt to occur. In a case of chronic pleurisy Dr. Wood tried to run off the water by the kidneys; the pulse ran down steadily from 70 to 40 in four days after the medicine had been withdrawn; it was a long time before the effect of the digitalis was manifested, and it was long before it ceased to act. In the pneumonia case, after the pulse began to drop, it was eighteen or twenty hours before it again reached the normal. The longer the digitalis is in acting the more likely it is to have a lasting effect. After abdominal tapping, the digitalis often shows itself in reducing the heart's action. Either the digitalis has been lying in the intestines unabsorbed or in the cellular tissue; probably all the fluids are saturated by the drug.

Digitalis is a very useful remedy in cases of syncope and collapse. Formerly alcohol alone was used. One of the advances of modern therapeutics was to teach the danger of giving large doses of alcohol in cases of surgical shock. *Belladonna* and digitalis are proper remedies given by the hypodermic injection. The pulse begins to fill up in twenty minutes or half an hour. No irritation is produced at the point of puncture. Throw in twenty minims of the tincture at once, and expect to find the result in half an hour.

He did not wish his remarks to be understood as declaring that digitalis was entirely without danger, but he had used it in hundreds of cases, and had seen men apparently dying revive under its effects. It is important to stop it as soon as evidence appears in the pulse that it is beginning to be absorbed. Used in this way, he did not believe that there would be any serious cases of poisoning with it.

Dr. Wood, in closing the discussion, said that he would refer to but two or three practical points that had been touched upon. First, in regard to the choice of preparations: the general preference seems to be for infusion. He believed that the only reason that the infusion was preferred as being more efficient is because it is usually given in relatively larger doses than the tincture. He would mention, in passing, that the infusion as well as the tincture obtained from an unknown druggist is not rarely an unreliable preparation. He had seen very few cases where the stomach disturbance was considerable, and believed gastric disturbance was less apt to occur when the tincture was given than with the infusion. With regard to digitalis, he had not made much use of it; it is not the alkaloid, but merely a purified extract, and comprises at least two principles, the one soluble in water, the other insoluble. It is uncertain in its composition and in its results. As the dose of digitalis is so small, it is not necessary to resort to this substance, with which you might get results or you might not.

He wished to be distinctly understood as discountenancing the use of large doses of digitalis until the small ones have failed; he would never use powerful remedies when milder ones will do. With regard to Dr. Seaman's case, the heart had apparently been starved, and the use of digitalis had flushed it with fresh blood, and gave it a new stock of nutrition. In such a case he would advise continuing the remedy, giving small doses from time to time, in order to continue the effect. The action of digitalis upon the frog's heart is that it is rarely arrested in diastole, more frequently in systole. As regards the question of its effect upon the pneumogastric nerve, in some cases the effect is to destroy life in this manner. In such cases we can restore the action of the heart by cutting the pneumogastric nerve. As a rule, however, the effect is greater upon the heart than upon the nerve, and the animal dies of cardiac spasm. It has the same effect upon the pulse of mammals; its full effect produces a weak pulse, sometimes dirotic; this he had seen beautifully illustrated in man. It means that there are two antagonistic effects upon the heart, upon the heart muscle and upon the brake action; this is undoubtedly the explanation of the dirotic pulse and of the double wave written upon the manometer. Later the arterial pressure is found to be falling; looking at the heart, the dilatation becomes less, the diastole becomes imperfect; only a small amount of blood now enters its cavities, on account of the cramp of the mus-

cular tissue, just as in the tetanic spasm or the muscles of strychnia poisoning; then comes cramp of the muscles of respiration and death. The pulse becomes frequent in digitalis poisoning, because the heart is so constricted that the blood is dammed back, and cannot get into the aorta.

#### INCISION OF THE PERICARDIUM.

Rosenstein<sup>1</sup> reports the following case, which was briefly alluded to in the *JOURNAL* of November 10, 1881. The patient was a boy ten years old. He had enjoyed good health till fourteen days before admission, since which he had suffered from gastric symptoms, cough, feverishness, and had taken to his bed. On admission his cheeks were white; lips and tongue pale red; skin moist; temperature 99.6° F.; pulse 108, small, very soft, regular; respiration 40, costal-abdominal; the left side of the chest in the mammary region bulged outwards; the apex beat could be neither seen nor felt, and the heart sounds were inaudible everywhere; percussion defined an area of dullness, roughly triangular, with the base downwards, commencing in the second left intercostal space, and extending on the left to the axillary line, on the right as far as the nipple; change from the recumbent to the sitting posture did not alter the shape or the size of the dull area; the lungs were normal; the liver was pushed outwards; the spleen was not enlarged; the bowels were regular; the urine was not albuminous. An exploratory puncture with Pravaz's syringe drew off a small quantity of pure pus, and on the evening of the same day urgent dyspnoea suggested the propriety of paracentesis, which was performed in the fourth interspace, close to the sternum, and more than twenty ounces of pure pus drawn off. The operation was followed by great relief, but of short duration. Fever of an intermittent type appeared, the evening temperature being 102.9° F., the pulse grew more frequent, and the urine became greatly diminished. This was due to serous effusion in the left pleural cavity, and as in a few days the dullness reached the supra-spino-fossa, the fluid (more than a quart) was removed by aspiration. A second puncture of the pericardium succeeded in removing only four ounces of pus. Percussion showed that the dull area varied with the posture; on sitting up it was two centimetres higher than on lying down. The heart sounds were feebly audible, and accompanied by slight friction. The general state of the patient was unsatisfactory. He slept badly, although the fever was slight (temperature 99.3° to 100.4° F.); his appetite was bad; the pulse was 120, small, irregular, unequal, and paradoxical; the respirations were 44, with orthopnoea; the lips and cheeks were cyanosed; the veins of the neck were swollen; there was some oedema of the scrotum and feet; the urine was scanty, but free from albumen. After consultation an incision was made in the fourth interspace, near the sternum, a little more than an inch in length, under strict antiseptic precautions, dissecting down layer by layer until the pericardium was exposed; this was punctured with the point of the knife, and the opening enlarged with a probe-pointed bistoury. A great quantity of pus escaped. Two drainage tubes were put in the wound, and Lister's dressing applied. The effect on the subjective condition of the patient was considerable, but the pulse remained very low, and the urine

scanty. On the day after operation the temperature was 100.4° F.; the dressings were changed on second, fourth, and seventh days. The pulse had now become regular, of fair volume, and the oedema had disappeared; the heart sounds were now distinctly heard, accompanied by friction. On the twentieth day after the operation the pericardial wound was healed. The left pleural cavity again became the seat of effusion, which was not purulent; afterwards a quart was removed without much improvement, and the fever having recurred, an incision was made, and fifty ounces evacuated, after which the patient remained free from fever, and was discharged two and a half months after the pericardial incision.

Professor Rosenstein draws the following conclusions from this case: (1.) Purulent pericarditis, like empyema, may occur without rise of temperature or oedema of the surface, so that only puncture can decide the diagnosis. (2.) The fear of some obscure changes in the myocardium should not deter us from evacuating such exudations. (3.) In accumulation of large quantities of fluid in the pericardium, change of posture may have no influence on the shape of the dullness.

#### TREATMENT OF INTRA-THORACIC SUPPURATING HYDATID BY INCISION AND EXTRACTION OF THE CYST.

Dr. L. D. Bird, of Victoria, communicated two cases to the Medical Society of Victoria<sup>2</sup> of intra-thoracic hydatid cysts which had advanced to the stage of death and decomposition, and were got rid of by incision between the ribs. Dr. Bird pointed out that this was a more complete and radical cure than tapping, or injections, or electricity, as we could never be quite sure, with the latter processes, that the vitality of the cyst had been completely destroyed, and its refilling, therefore, rendered impossible. But extraction was a far more serious and difficult operation, and only justifiable under certain conditions. The first of these was that the hydatid should be in the pleural sac, for then the cyst always enlarged with great rapidity, and even when emptied of its contents, or dealt with in any way short of removal, remained a permanent source of irritation to the serous surface, giving rise to pleuritic pains, with fever and even inflammatory effusion. The question, of course, had to be faced of the possibility of diagnosis between a pleural hydatid and one in the lower lobe of the lung, or on the convex surface of the liver, especially in the right side. Usually in pleural hydatid the rounded area of dullness is altered somewhat by change of position, which would not happen were the cyst imbedded in lung substances.

Other conditions were the existence of large, old suppurating cysts of the lung, which had found their way into a bronchus, and led to the expectoration of fragments of cyst and fetid pus, with much difficulty and distress to the patient. Such cases usually occurred in the lower lobe. Adhesions were almost constantly found, and operation was comparatively safe and easy. He had seen more than a dozen such cases which had resulted in complete success. The following cases, one of pleural and the other of pulmonary hydatid, treated in this way, had not hitherto been published:—

A married lady, aged twenty-six, suffered from a

<sup>1</sup> Berl. Klin. Woch., 1881, No. 5. London Medical Record, No. 79, N. S.

<sup>2</sup> The London Medical Record, No. 74, N. S.

condition variously diagnosed as pleuritic effusion, liver enlargement, and abscess. The right side measured an inch and a half more than the left; there was no history of acute pleuritis; pains, however, of a stitichy, pleuritic character were felt all over the side. A rounded area of dullness, characteristic of hydatid, was found in the lower part of the right chest. Breath sounds and percussion note were normal at the apex, even when the hips were raised above the level of the thorax. A trocar was introduced in the seventh interspace, and three pints of semi-purulent fluid escaped, containing abundant hooklets on microscopic examination. This did not give much relief, and some ill-defined dullness was left about the base of the right lung, with pleuritic stitches, a quick pulse, and high temperature, showing a local source of irritation in the pleura. Dr. Bird was now convinced that it was a case of pleural hydatid, and determined, in conjunction with Dr. Martin, to remove it. The tenth day after the first tapping a free incision was made between the seventh and eighth ribs, and a large semi-decomposed hydatid cyst, broken into several fragments, was removed without difficulty. A few ounces of pus and broken-down fragments of hydatid followed the main cyst, and then rather a free discharge of venous blood, which soon ceased. A piece of drainage tube was left in the pleura. Great relief followed this operation; fever and pain disappeared, and there were no physical signs of any further foreign body in the cavity of the chest. But a fortnight after the patient began to complain again of dyspnea and oppression, and on exploring the cavity of the pleura with an elastic catheter another cyst was burst into, which discharged about ten ounces of perfectly clear hydatid fluid swarming with echinococci. This cyst also was removed, and the pleural cavity irrigated with weak solutions of iodine. Great relief followed, but, unhappily, symptoms indicative of hydatid in the pericardium ensued, namely, sudden and alarming attacks of dyspnea, ending in syncope, with cardiac murmurs terribly jumbled and confused. These increased in intensity, till, in one of them, she died suddenly, the pleura and lung being apparently restored to their normal condition. There was, unfortunately, no post-mortem examination.

The other case was one of hydatid of the lung substance. A girl, aged nine years, suffered from excessive emaciation, with intense hectic and quick pulse, constant violent cough, and expectoration of pus and fragments of cysts, of horrible fetor. She could only breathe lying over partially prone on the affected side. A large trocar was introduced between the fifth and sixth ribs, and many ounces of fetid pus and fragments of cyst escaped, and great relief followed. After two days the opening was enlarged and the parent cyst was removed; a piece of drainage tube was left in the *nidus* of the parasite, and this was often washed out with weak Condy's fluid. In less than a month the child returned to her home in perfect health, the wound having healed up from the bottom.

Dr. Bird, in answer to objections, said that even when diagnosis of site can be made with certainty, it must be remembered that simple tapping leaves the cyst intact, and as this shifted from side to side with every movement, the cavity must refill or pleuritic irritation be set up. Suppuration was sure to take place, and then, with empyema plus a cyst, the old necessity for operation remained. As to iodine, it could not be injected into cysts of this kind in any

strength. He had seen thirteen cases of old suppurating hydatids within the chest treated by incision, and only one died. In that case the cyst was the largest he had ever seen. At the first tapping one hundred and fifty-six ounces of fluid were withdrawn, and when the cyst was subsequently removed it weighed a pound, yet the case was practically cured; but there was erysipelas in the hospital, and the very afternoon the patient was preparing to leave, a blush appeared around a small fistulous tract that remained, and septicæmia and death followed. At the post-mortem examination, notwithstanding the enormous pressure which must have been exerted by so huge a cyst, the lung had again expanded.

## Hospital Practice and Clinical Memoranda.

### A CASE OF TYPHILITIS WITH GENERAL PERITONITIS; AUTOPSY.

BY ASSISTANT-SURGEON C. T. FICKHAM, UNITED STATES MARINE HOSPITAL SERVICE, NEW YORK.

J. R., Russian, twenty-seven years of age, applied at the United States Marine Hospital Office, New York, January 13, 1882. He stated that he had some pain in his bowels, and that his bowels were loose. He said he had had five or six dejections during the last twenty-four hours. He was given a diarrhoea mixture and told to call again on the day following. He did so and said his pain was worse. He was sent to the Hospital, January 14 where I saw him at seven P. M.

He then complained of a severe pain in the right iliac fossa. He had no diarrhoea, he said. This pain was all that troubled him. On examination I found that the right iliac fossa was fuller than the left, that there was much tenderness and some dullness in the right iliac fossa. His face wore an anxious expression, and the leg was drawn up on the affected side.

His respirations were 38 per minute, pulse 140, and temperature 37.9° C.

January 15th, ten A. M. Patient in a stupor all night. Tenderness over whole abdomen. No pain complained of. Pulse 160, weak and thready, temperature 38° C., respiration 40. Seven P. M., some vomiting after taking a large quantity of ice-water. Pulse 150 and of same character as at the morning visit, respiration 44, temperature 38.8° C.

January 16th, ten A. M., patient much oppressed; says he cannot breathe. No pain. Tenderness great; cannot bear the weight of a light poultice. Feet and hands cold, and bathed in a profuse cold perspiration. Pulse 160, respiration 56, temperature 39° C. Seven P. M., patient weaker than at the morning visit. Has not vomited as much as he did during the night. Pulse 160-180 and feeble, respiration 60, temperature 38.6° C. Otherwise the same as at the morning visit.

January 17th, ten A. M., patient weaker. Pulse 170-200 and scarcely to be detected, respiration 60. While I was in the ward he had one tonic convulsion, gasped a few times and died.

Autopsy twenty-four hours after death. Rigor mortis well marked. Dependent parts of body very purple. Body is that of a strong man.

Peritoneum much congested and dull looking. Small intestines everywhere adherent and in many places covered with false membranes. Omentum adherent to small intestines. At the lower part of the

abdominal cavity was a cavity bounded by the bladder below, laterally by the iliac bones and their muscular coverings, superiorly by the small intestines pushed up and covered by false membranes. This cavity contained about one and one half litres of purulent fluid of very fetid odor. By carefully raising the small intestines and omentum I found the cœcum not much congested, and the appendix vermiformis apparently normal for one half its extent. In its third fourth counting from the cœcum there was a black slough, and when I very carefully raised it what appeared to be a date stone remained behind, above the brim of the true pelvis on the iliacus muscle. This body by careful examination proved to be hardened fecal matter. The omentum was attached to the appendix vermiformis and the part so attached was also black and sloughing. The appendix was curved on itself but was everywhere patent, as water easily flowed through from the cœcum to the abdominal cavity before the appendix was disturbed.

### Reports of Societies.

#### PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, SECRETARY.

##### SURGICAL SECTION.

JANUARY 7, 1882. DR. R. M. HODGES presiding. DR. JOHN HOMANS read a paper entitled

A CASE OF LISTERIAN OVARIOTOMY IN WHICH THE BLADDER WAS FREELY LAID OPEN; UNINTERRUPTED RECOVERY.

Vide JOURNAL, page 153.

DR. J. W. ELIOT said that he could add two cases to the list of the reader, where he had seen a distinguished continental surgeon open the peritoneal cavity in the high operation for stone. Both cases terminated fatally, and it was interesting to note that in both cases the mucous membrane of the bladder was included in the stitches. We may learn from the history of the operation for vesico-vaginal fistula how unsatisfactorily a wound of the bladder heals if the mucous membrane is included as was the case before DR. J. Marion Sims demonstrated its impropriety.

The recent success in uniting wounds of the intestines is also here instructive as showing the advisability of bringing together the peritoneal surfaces.

DR. POST said that Dr. Vincent, in the articles quoted by the reader, laid great stress on bringing together the peritoneal surfaces in sewing up wounds of the bladder. Dr. Vincent says, in speaking of the use of one particular stitch which brought the peritoneal surfaces well together, that with this stitch he had never failed to obtain union in his experiments on dogs.

DR. A. N. BLODGETT asked whether in the cases where urine had been extravasated, enough time had elapsed to allow of decomposition taking place.

In reply DR. HOMANS said that in the only case where recovery in a male had been reported, at the time of the operation peritonitis had already set in, and that free urine was found in the peritoneal cavity; this was sponged out and a catheter placed in the bladder to keep it empty. The wound in the bladder was not interfered with.

DR. A. N. BLODGETT referred to the absence of

bad effects from the presence of urine in the abdominal cavity, and mentioned a case which had recently come to autopsy, where there was a perforation of the anterior vesical wall, which from all appearances must have opened directly into the peritoneal cavity. The wall of the bladder then evidently became adherent to the parietal peritoneum by localized peritonitis about the perforation, and the extravasated urine could no longer pass into the abdominal cavity but had burrowed into the groin, and from thence had dissected the entire musculature from the pelvis to the knee, causing death by septicæmia and exhaustion.

There was not a trace of either old or recent peritonitis excepting at the point mentioned, where the localized protective inflammation had united the adjacent surfaces of peritoneum, thus acting as a safeguard against the continued leaking of urine into the abdominal cavity. Whatever urine had been extravasated into the peritoneum had been completely removed by absorption without leaving a trace of its existence.

DR. GAY asked the reader's experience in regard to the use of silk sutures left in the abdominal cavity.

DR. HOMANS answered that he had never had any trouble from them. In one case he had been present at the autopsy of one of his patients twelve months after the operation for ovariectomy, — the woman dying of heart disease. In this case the pedicle was found to be very thick, and was tied transversely and around with a silk ligature at the time of operation. At the autopsy no trace of the ligature was visible; the right ovary was absent, and the only evidence of the operation was a shiny white line about one half an inch long, — the scar left by the ligature, — near the end of the right broad ligament. In a second case, where the autopsy was six months after the operation, no trace of the silk was found. Dr. Homans suggested that raw silk, being an animal product, so to speak, that is, — the gut of a worm, — might be absorbed as well as ordinary catgut.

DR. C. W. WOOLDRIDGE asked whether the peritoneum was folded down between the bladder and the abdominal wall.

DR. HOMANS answered that it was drawn up, there being no peritoneum between the bladder and the rectus muscle till about one and one half inches above the umbilicus.

DR. KINNEAR asked what was the explanation of the union being better when the mucous membrane was not included.

DR. HOMANS thought it was due to the avoidance of fistulous connections which might form in the track of the stitch.

DR. GAY spoke of a case where the angle of the mouth was split back to gain room in removing a new growth from the jaw; in sewing up, part of the stitches included the mucous membrane, part did not. In the former portion perfect union took place, in the latter there was no union.

DR. J. W. ELIOT thought that the mucous membrane, being very sensitive, the irritation of the stitch caused the bladder to contract and expand spasmodically, thus preventing union.

DR. HOMANS stated, that although naturally very anxious about the patient, he was agreeably surprised to find no unfavorable symptoms at his visit the day following. Fever was absent throughout; convalescence was rapid and the woman was able to return home in less than three weeks.

DR. HODGES, in closing the discussion, recalled the remarkable series of cases of impalement formerly reported by Dr. J. B. S. Jackson. In one of these, at least, the bladder was torn open and into the peritoneal cavity; yet recovery took place. In speaking of the method of sewing up vesico-vaginal fistulae, the chairman reminded the section that this was first practiced by Dr. George Hayward, of Boston, at the Massachusetts General Hospital. Hayward was also the first successful operator in the country on a vesico-vaginal fistula. Dr. Hodges said that there was a general impression, stronger formerly than at present, that the passage of urine over a wound was detrimental to the healing process. Yet in lithotomy and vesico-vaginal fistulae the wounded parts are constantly bathed in urine without untoward results, and in many of these cases, too, the urine has undergone decomposition, yet no harm ensues.

DR. A. T. CABOT presented a communication entitled

#### OSTEOTOMY AND OSTEOCLASIS; CASE AND SPECIMEN.

Vide JOURNAL, page 155.

The reader described a case operated on by Macewen's method, with very satisfactory results, perfect union occurring in three weeks; the patient died soon after of typhoid fever, and the specimen was exhibited, showing perfect union of the bones in a corrected position.

DR. POST spoke of a case which he had operated on by Macewen's method with results very similar to those described by Dr. Cabot. He was obliged to change the dressing on account of soakage, and this probably interfered with the healing of the flesh wound, which failed to unite by first intention. There was a rise of one degree on the second day: the temperature fell to the normal the next day, and remained so. The bone was found solidly united in three weeks, at which time the plaster was removed. Dr. Post spoke of several cases operated on in New York by this method without antiseptic precautions which did well.

DR. A. N. BLODGETT asked how the distance to which the chisel had penetrated could be accurately determined.

DR. CABOT explained the chisel used, which is marked off into inches and half inches: this enables the operator to determine the exact distance the chisel has penetrated the bone.

DR. BLODGETT asked if in the first case spoken of by Dr. Cabot, the possibility of a causal relation between the wound of the bone medulla and the general tuberculosis had been considered. Dr. Cabot replied that it had not been deemed probable; the time between the operation and death being three weeks.

DR. E. H. BRADFORD called the attention of the section to the value of the specimen exhibited by Dr. Cabot. He thought it unique in being so recent as to show perfectly the method of cure, and yet sufficiently old to evidence a cure of the deformity. Dr. Bradford said at the time of the operation, when assisting Dr. Cabot, he thought the chisel had not been driven through far enough, too much of the bone being broken. In the light of the specimen he was convinced that Dr. Cabot had acted wisely.

DR. BRADFORD said that in a case of knock-knee, where the patient was too old for a correction of the deformity by the use of appliances alone, the choice lay between: first, correction by tenotomy of the exter-

nal ham-string tendons, and the subsequent continued use of a strong mechanical power, which would force the limb into position; second, forcible straightening; third, osteotomy. In a certain number of cases treated according to the first of these methods a relaxed condition of the knee-joint follows, impairing the usefulness of the joint. Experiments on cadavers have shown that in a comparatively large proportion of cases of forcible straightening rupture of the lateral ligaments takes place, with a consequent injury to the joint; this has also been proved by clinical experience in adults; in children the results are good, but the method lacks precision, and it is always impossible to determine whether the separation of the bone will take place at the femoral or tibial epiphysis.

Statistics seem to show at present that the danger from osteotomy, when properly performed, is very slight, and the results are excellent. Of the different methods of procedure that of Macewen is certainly the best. In the six operations for osteotomy which Dr. Bradford had had an opportunity for performing, the reaction was hardly greater than after tenotomy, and the results had been exceedingly satisfactory. In one patient the whole femur had been accidentally divided in an osteotomy instead of three quarters of the thickness with subsequent fractures, as recommended by Macewen, and in consequence union was delayed. In a subsequent case, where the operation was more precisely done, there was good union in four weeks.

DR. H. I. BOWDITCH showed a device for the prevention of slipping by the insertion of a small cylinder of solid India-rubber inserted into the heel of the shoe, the flat surface projecting slightly below the level of the heel.

#### Recent Literature.

*The Nurse and Mother. A Manual for the Guidance of Monthly Nurses and Mothers.* By WALTER COLES, M. D., St. Louis. St. Louis: Published by J. H. Chambers & Co.

The hundred and fifty pages of this book contain just enough of the scientific language and ideas of obstetrics to promote a pleasing, but dangerous, self-confidence among mothers and untrained nurses, and to tempt them, in too many cases, to usurp the duties of the medical attendant. The nurse who, following the advice, only "strives against making any comments calculated to excite the distrust of the sick, or bring the physician under whom she is serving into unfavorable comparison with others," and who "makes her comments privately to the physician" upon the treatment, could hardly anticipate many engagements under the same practitioner. The manual has little value for the nurse educated in lying-in wards. The chapter on emergencies is the most useful portion of the work.

*A Practical Manual of the Diseases of Children, with a Formulary.* By EDWARD ELLIS, M. D. Fourth Edition. Revised and Enlarged. Philadelphia: Presley Blakiston, 1012 Walnut Street. 1881.

The last edition of this manual appeared in 1878, and was then revised and enlarged in many parts. The present edition has little of practical importance that is new, and retains the characteristic of the original work in being essentially a compendium largely made up of quotations from the writings of other authors.

# Medical and Surgical Journal.

THURSDAY, FEBRUARY 16, 1882.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

## WAS THE LIFE-LONG MALADY OF DEAN SWIFT MÉNIÈRE'S DISEASE?

In the last number of *Brain* Dr. Bucknill, one of the editors, discusses the maladies of Dean Swift in an article which throws much light upon the strange character of that singular but gifted man, and at the same time is an interesting illustration of one of the recent triumphs of pathological research directed by physiological experiment.

Dr. Bucknill states, as an explanation of his reopening a subject which might fairly be regarded as threadbare, and concerning which many would consider that everything had been said which ought to have been and not a little which ought not to have been said, that he received a letter last autumn from a gentleman engaged in literary work requesting his opinion on the "mysterious disease" of the great author and wit, and asking particularly whether the sane part of Swift's life was likely to have been in any way affected by the latent presence of insanity; whether a correct diagnosis was possible; whether parallel cases were on record; and, finally, whether a surfeit of green fruit, at the age of twenty-three years, was capable of resulting in the absolute fatuity from which the patient suffered at seventy-five.

Stimulated by these inquiries he investigated the subject anew, with the result that he thinks upon weighing the evidence it will probably be acknowledged that Jonathan Swift's mysterious disease was an instance of labyrinthine vertigo or Ménière's disease.

Various passages are quoted from biographies of Swift by Forster and by Sir William Wilde, the accomplished father of an æsthetic son, to support the theory of his disorders advanced by Dr. Bucknill, the original cause of which it is claimed lay in a cold got before he was twenty years old. Swift himself writes under date of April 30, 1737, when in his seventieth year: "In England before I was twenty I got a cold, which gave me a deafness that I could never clear myself of. . . . My left ear has never been well since."

Forster, in his biography, makes the following quotation from one of Swift's note-books:—

"1708. *Nor.*—From 6th to 16, often giddy. G<sup>d</sup> help me. So to 25 less. 16, Brandy for giddiness 2s. 18th 3d. *Dec.* 5.—Horribly sick. 12th.—Much better, thank God and M. D.'s prayers. 16th.—Bad fit at Mrs. Bartons. 24. Better; but dread a fit. Better still to the end. 1709, *Jan.* 21st.—An ill fit

but not to excess. 29. Out of order. 31. Not well at times. *Feb.* 7.—Small fit abroad. Pretty well to the end. *March.*—Headache frequent. *April* 2nd.—Small giddy fit and swimming in the head. M. D. and God help me. *August.*—Sick with giddiness much. 1710. *Jan.*—Giddy. *March.*—Sadly for a day. 4th. Giddy from 4th. 14th.—Very ill. *July.*—Terrible fit. G<sup>d</sup> knows what may be the event. Better towards the end."

He often described himself as

"Vertiginosus, inops, surdus, male gratus amicis,"

but naturally never appears to have associated his vertigo with the state of the auditory organ.

Various passages in support of Swift's having been the victim of Ménière's disease occur in the course of his *Journal to Stella*, written between the years 1710 and 1713, while he was residing in London. Under date of October 31, 1710, he writes: "This morning sitting in my bed I had a fit of giddiness; the room turned round for about a minute, and then it went off, leaving me sickish, but not very. I saw Dr. Cockburn to-day, and he promises to send me the pills that did me good last year; and likewise has promised me an oil for my ears, that he has been making for that ailment for somebody else." On this Dr. Bucknill remarks, "A fit of giddiness, with sickness and ear-disease, is not this labyrinthine vertigo?" and continues:—

On different days in January, 1611, Swift writes:—"I had an ugly fit in my chamber last night." . . . "My head is not in order, and yet is not absolutely ill; but giddyish, and makes me listless." . . . "One fit shakes me a long time." *Feb.* 1.—"I walked into the City to dine, but I walked playfully carefully, for fear of sliding against my will." *April* 18.—"I did not go to the House of Commons about the yarn: my head was not well enough. I know not what is the matter. It has never been thus before; two days together giddy from morning till night, and I totter a little, but can make a shift to walk."

In *May*: "I do not totter as I did, but walk firm as a rock, only once or twice for a minute."

*Sept.* 1st he notes an important peculiarity, distinguishing cerebral from stomachic vertigo:—"My head is pretty well; only a sudden turn at any time makes me feel giddy for a moment, and sometimes it feels very stuffed."

The journals of October show that he distinguished ordinary from vertiginous headache:—"My head has ached a little in the evening, but it is not of the true giddy sort, so I do not much value it." . . . "I had a little turn in my head this morning, which, though it did not last above a minute, yet being of the true sort, has made me as weak as a dog all this day."

During the years of residence in London which embrace the period of the "Journal to Stella," his other enemy, deafness, is only referred to incidentally, as when he compares it to that of the Lord Treasurer; but after his return to Ireland, his deafness becomes sufficiently severe to make him complain.

In 1720 he writes:—"What if I should add that once in five or six weeks I am deaf for three or four days."

In 1724 he writes:—"I have been this month past so pestered with a return of the noise and deafness in my ears that I had not the spirit to perform the common offices of life." Subsequently, in the same year: "My deafness has left me above three weeks, and therefore I expect a visit from it soon." It was evidently periodic and paroxysmal, like the giddiness.

He complains in another letter of an old vexatious disorder of a deafness and noise in the ears. In 1727, in a letter to Sheridan, he says that his deafness is worse than it ever before had been, and that it is accompanied by giddiness and tottering. "I believe," says he, "that this giddiness is the disorder which will at last get the better of me." And again, "I walk like a drunken man, and am drier than ever you knew me."

In 1728, in "about eight months," says Wilde, "he had half a dozen attacks of the giddiness and sickness, each of which

lasted about three weeks." But in 1731 he wrote to Mr. Gay, "The giddiness I was subject to, instead of coming seldom and violent, now constantly attends me more or less, though in a more peaceable manner, yet such as will not qualify me to live among the young and healthy." In 1736, writing to Pope, "years and infirmities have quite broke me. I mean that continual disorder in my head." In 1737, to Alderman Barker, "I am forced to tell you my health is much decayed; my deafness and giddiness more frequent; spirits I have none left; my memory is almost gone."

Long before, however, these symptoms had commenced. Impairment of memory he complained of as early as 1713, after the attack of shingles; and later on in the same year he speaks of his horrible melancholy changing into dullness, and from thenceforth increasing irritability of temper and mental depression are traceable throughout his history and correspondence. Not that he was at any time really of unsound mind or incapable; for when in 1737, in the Bettesworth affair, a gratifying address was presented to him, it is recorded that "when this paper was delivered Swift was in bed, giddy and deaf, having been some time before seized with one of his fits; but he dictated an answer in which there is all the dignity of habitual pre-eminence and all the resignation of humble piety."

The above quotations are but a selection from a far greater number of references which might be made to Swift's letters and journals, affording conclusive evidence, as I venture to think, that he suffered from twenty years of age from the disease, whose characteristic symptoms are, "that the patient is suddenly seized with vertigo and a feeling of nausea or positive sickness, with great constitutional depression and faintness. Usually the giddiness comes on simultaneously with ringing or buzzing in one or, it may be, both ears." — Ferriér.

It has this year been pointed out by Féré, in the *Revue de Médecine*, that there are two forms of the disease to be recognized, "une forme grave avec état vertigineux à peu près permanent interrompu par les paroxysmes, et une forme moins fâcheuse, constituée par des accès séparés par des périodes de santé parfaite." "Dans la forme bénigne (of which Swift's was an example) les accès ne se produisent quelquefois qu'à de longues distances très éloignées. E. Ménière cite une malade qui eut une rémission de onze mois. Pendant ces périodes d'accalmie, la surdité persiste avec une intensité variable, et elle s'accompagne souvent des sensations subjectives intermittentes de l'ouïe. La maladie elle-même dure tant que la surdité n'est pas absolue."

Up to the date to which we have traced the progress of the disease, it appears to have been purely a physical malady, with no mental symptoms, unless some degree of loss of memory can be so called. Swift, indeed, complains bitterly of the impairment, as if memory were gone, and in his declining years of age and sickness it may have been a dull function compared with the brilliant faculty he once possessed. But clearly the memory was still serviceable which enabled him to compose, with wonderful vivacity, even such poetry as that outburst against political and social corruption — "The Legion Club." . . . That disease and grief had made him irritable and passionate, and often desponding, is clear enough from his correspondence and the accounts of him which have come down to us; but that there was any failure of mind this "Legion Club" fully disproves; and if fiercely expressed hatred is any evidence that an author is on the verge of insanity, Jeffrey must have been curiously insensible to the testimony he was bearing against his own soundness of mind in his criticism of the greater master of his own art.

Between 1736, when Swift wrote "The Legion Club," and 1741, when the outbreak of insanity really took place, there can be no doubt that he passed through a period of great wretchedness and depression, — he was "miserably ill." He had lost to a great extent two of his senses, for he was deaf and his eyesight failed; his dearest friends had died before him, and his public sympathies were constantly outraged.

In 1738 he wrote Alderman Barker, "I have for almost three years past been only the shadow of my former self, with years of sickness and rage against all public proceedings, especially in this miserably oppressed country. I have entirely lost my memory, except when it is aroused by perpetual subjects of vexation."

Two years later he wrote the following pathetic letter to his old friend Mrs. Whiteway: —

"I have been very miserable all night, and to-day extremely deaf and full of pain. I am so stupid and confounded that I cannot express the mortification I am under, both of body and mind. All I can say is that I am not in torture, but I daily and hourly expect it. Pray let me know how your health is, and your family. I hardly understand one word I write. I am sure

my days will be very few; few and miserable they must be. I am, for these few days, yours entirely, J. SWIFT."

"If I do not blunder it is Saturday."

A very pitiful state this period of becoming insane, and yet not having become so. But even at this late date one cannot recognize the invasion of mental disease. Misery and despondency there was, more than enough, but not madness, unless Job was mad. But Swift was rapidly tending toward madness.

It was not until 1711 that Swift developed positive symptoms of actual cerebral disorder, which increased until his death, on October 19, 1745, in the seventy-eighth year of his age. An autopsy was performed, and a plaster cast taken of the face and of the inside of the skull. The only record of the autopsy is that "much water was found in the brain." In regard to the plaster cast Sir William Wilde says: "The expression is remarkably placid, but there is an evident drag on the left side of the mouth, exhibiting a paralysis of the facial muscles to the right side."

Connecting these authentic records with the report of one of Swift's attendants, which disclose symptoms of aphasia, Dr. Bucknill remarks: —

With all the tortures of the life-long disease from which he suffered, and its obvious effect upon his temper in his later years, it is wonderful that Swift did retain his reason until, in the seventy-fourth year of his age, he was in all probability struck down by a new disease in the form of a localized left-side apoplexy or cerebral softening, which determined the symptoms of his insanity.

It is enough now that we can diagnose his life-long disease as labyrinthine vertigo, and his insanity as dementia with aphasia, the dementia arising from general decay of the brain from age and disease, the paralysis and aphasia from disease of one particular part of the brain.

It is certain that this fearful disease, aggravated with the increase of years, had an influence in the causation of Swift's insanity, but that its influence was direct, that is to say, by the extension of the local disease to the brain, is by no means so sure as its indirect effect as one source of the profound depression which marked the latter years of his sane life.

According to this account of Dr. Bucknill, the disease, as manifested by the great Irish dean, if true labyrinthine vertigo of Ménière, was of the mild form described by Féré, as a rule paroxysmal in character, though at times re-occurring more frequently, and increased in frequency with advancing years.

Ménière's attention was first attracted to the form of disease which now bears his name, in 1861, by Fleuren's experiments upon the semicircular canals of pigeons, and it would certainly be not a little curious and interesting should we be led, by the light of modern physiological experiment and pathological research, to revise our conceptions and estimate of a great historical and literary personage of a previous century, who exercised a marked influence upon the history of his day, and whose singular career was an enigma to his own contemporaries, and has continued such to succeeding generations. The suggestions contained in the article of which we have given an abstract at least inculcate the wisdom of being slow to judge, and illustrate the value of physiological experiments.

# THE ANNUAL MEETING AT ALBANY OF THE NEW YORK STATE MEDICAL SOCIETY.

THE chief medical events of the past week which deserve notice are the convention of the State Medical Society and the meeting of the State Board of Health, including the annual report to the governor and legislature at Albany.

One of the most important meetings of the Medical Society of the State of New York that has ever been held terminated on the 9th inst., after having been in session three days, important not so much on account of the number of papers read, which was great, but on account of measures which were adopted affecting the professional status of "irregulars," and the interests of the general practitioner. Although not so large as the previous meeting, there being only four hundred and twenty-eight names on the register, yet unusual activity and interest was displayed; evidently those in attendance meant business, especially the delegates from New York city. While they gained their avowed object of releasing themselves from the authority of the code of ethics of the American Medical Association, it yet remains to be proven whether the gain is not more than balanced by the loss. The provisional code offered and adopted at this meeting permits consultation with all physicians practicing under the laws of the State of New York, but seeks to atone for its liberality in the matter of consultations (which bring in fees) by condemning as reprehensible the giving of certificates for copyrighted or "proprietary" drugs, medicines, wines, mineral waters, health resorts," etc. (which, by the way, yield no fees), an inconsistency which was pointed out in the discussion by Dr. Squibb, of Brooklyn, who could not understand why the professed liberality should stop short with the matter of consultations.

The matter of compulsory registration of all practicing physicians was again taken up in connection with a communication from the New York County Medical Society, which pointed out the fact that the law of 1880 is inoperative against a certain class of irregular physicians. After considerable discussion the entire subject was referred to the committee on legislation. In the same communication the subject of the establishment of a State examining board, which should alone have the power to issue licenses to practice, was strongly urged, and was also advocated in the president's inaugural address, and in a paper read by Dr. Sturgis, the president of the New York County Medical Society. It is hoped that the legislature at its present session may pass such an efficient law without having it rendered inoperative at the last moment by the addition of some amendment intended to defeat its object.

Among the scientific papers of especial interest read at this meeting those by Austin Flint, Chas. S. Bull, L. D. Bulkley, and C. R. Agnew, with the president's address, are deserving of mention.

— A new street in Paris, situated in the *arrondissement* in which Littré died, is to be called after him la Rue Littré. It will be opened into the end of the Rue de Rennes.

## MEDICAL NOTES.

— One fact in connection with the meeting of the New York State Medical Society that indicates the enterprising character of modern medical journalism, was that a full report of its proceedings appeared in the *Medical News* of Philadelphia, issued on the day after the meeting adjourned, by telegraph from a special reporter. The *Albany Medical Annals* issued as usual a daily edition containing the proceedings of the session.

— The total number of small-pox cases known to exist in Boston on Tuesday last was four. Seven cases in all were reported during the month of January. Seventeen thousand two hundred and twenty-three gratuitous vaccinations have been done under the auspices of the Board of Health since January 1st.

— Three physicians of Boston have recently been the victims of serious accidents: Dr. Arthur H. Nichols has fractured his malar bone, Dr. Edson has received a compound fracture of the leg, caused by ice falling from the roof, and Dr. O. F. Wadsworth has a fracture of the patella, due to a fall on the ice, and in addition Dr. Charles Homans was struck on the head by a bottle in the hands of an unknown assailant on Saturday night last.

— "L'entrée est défendue aux dames" is certainly not a suitable inscription to be placed over the portals of a University; and it is satisfactory to be assured by the President of the Boston University, in his last report, that a phrase so often seen over certain apartments in French railway stations will be denied a place upon the front of the University building.

— On the night of Friday, January 27, considerable damage was done to the wires of the Fire Department, in New York, by their coming in contact with those of the United States Electric Light Company. Repairs were made, but on the following night some of the fire boxes were again injured. Not until Sunday was the cause discovered. It proved to be a point of contact between the two systems of wires, scarcely one-sixteenth of an inch wide. The constant rubbing of the wires had gradually worn away the insulating material of the electric light wire. The Fire Commissioners have passed a resolution asking information of the Corporation Counsel as to "whether the companies furnishing electric light can be restrained from running their wires under, over, or across the wires of the department, and whether they are liable for damages, and what remedy must be applied." The telegraph wires connecting the fire boxes should be protected at any cost from all possible danger of accident. If the electric light companies cannot run their wires across those of the Fire Department, their only alternative seems to be the adoption of the underground system. — *Sanitary Engineer*.

— For the purpose of determining how far the prevalence of small-pox in the several States is due to the introduction of the disease into the United States from other countries, or from one State into another, and what measures would most effectually prevent its introduction from other countries, and spread from one State into another, the National Board of Health has submitted several inquiries to State Boards.

## WASHINGTON.

—A motion made in the House of Representatives, January 17th, to take the bill to incorporate the Garfield Memorial Hospital out of its regular order on the calendar and have it passed, met with decided opposition, which resulted in the motion being negatived, and the debate which ensued developed a good deal of doubt in the minds of members as to its utility and necessity, and a fear of establishing another claimant for yearly appropriations from Congress. Some of the grounds taken were rather ludicrous, and others seemed to show the promptings of other interests which naturally might clash with this. The act of incorporation did not have connected with it in any way any clause looking to present or future appropriations from Congress, although it is very probable that such appropriations will in time be asked for. Curiously enough strenuous objection was made to that clause in the act which threw open the doors of the hospital to non-residents of the District, when the only respectable general hospital in the District has for years had an annual appropriation for non-residents but none for the resident poor; it was supposed that Washington would, upon the passage of this act, be immediately flooded with all of the sick pauperdom of the United States that could beg or steal a passage to this Mecca. Mr. Cobb, of Indiana, laid much stress upon this, giving Washington a population of 176,000 and a pauper list of 31,000; but he did not say what he might have stated, that Congress itself is directly responsible for a large proportion of this pauperism by encouraging men to travel long distances from their homes with the fallacious hopes of getting offices founded upon the promises of politicians as their representatives; by putting individuals in office to enjoy salaries far exceeding in amount what they have ever been accustomed to, giving them expensive and luxurious habits, and, when the spirit of ambition has died out within them, and they are unfitted for any other kind of life, turning them out of office to make room for some one else; that this has led in some cases to something worse than pauperism, that prostitution has had its ranks increased by just such causes.

**HOSPITAL RECORDS; SURGEON-GENERAL'S OFFICE.** A resolution calling for a proper index for these records was offered January 23d in the House of Representatives, and referred to the proper committee. Mr. Taylor, of Ohio, in offering the resolution, stated that these records formed some sixteen thousand volumes and a mass of bed-cards, hospital reports, reports of casualties in battle, hospital muster rolls, etc., and that they were rapidly being made illegible from constant reference and re-reference for the want of a suitable index, it not being unusual to have searches made a dozen times over in a single case; the clerical force of about one hundred and sixty clerks in the surgeon-general's office is not sufficient for such work, and the resolution is offered in the interest of the Pension Bureau, and to lessen expenses in the surgeon-general's office.

**DISTRIBUTION OF VACCINE VIRUS.** Both houses of Congress have passed a bill appropriating fifteen

thousand dollars for the purchase of vaccine virus to be designated as pure by the National Board of Health, and to be furnished by the said Board to all persons applying for it at cost price, the proceeds to be paid into the treasury.

**MUSEUM OF HYGIENE.** The Bureau of Medicine and Surgery, Navy Department, has issued a circular, stating that the surgeon-general has established a Museum of Hygiene, which the American Public Health Association has made its permanent central repository.

The circular states that "It is intended that it shall exhibit the present state and future progress of the nation in all departments of hygiene," and asks the coöperation of all interested in sanitary matters by contributions of whatever tends to the preservation of health and the prevention of disease. Medical Inspector A. L. Gihon is directly in charge of the collection, and a large room has been devoted to its present uses.

This opens up a very extensive and useful field, and if fully carried out must excite great interest, and furnish the basis for a distinct branch of medical education.

**FIRE-PROOF BUILDING FOR THE ARMY MEDICAL MUSEUM AND LIBRARY.** The surgeon-general of the army has submitted to Congress the plans and estimate, amounting to three hundred thousand dollars, for the purchase of a site and the erection of a fire-proof building to contain the records, library, and museum of the surgeon-general's office. His accompanying statement sets forth that the space now available has become quite inadequate, not merely for proper display, but even for satisfactory storage, that the building is not fire-proof, and that it is surrounded by, and in immediate contact with, inflammable houses and sheds, which are on private property.

The library now contains about 51,500 volumes and 57,000 pamphlets relating to medicine, surgery, and allied topics, and many of these, if destroyed, could be replaced with great difficulty and cost. The collection of the Army Medical Museum consists of 22,000 specimens, and is unique in the completeness with which both military surgery and the diseases of armies are illustrated. The hospital records of 16,000 bound volumes, and a mass of other papers, serve greatly to the protection of the government, and to the advantage of many claimants; once destroyed there is no replacing them.

Surgeon-General Barnes has shown very happily and forcibly, in his accompanying report, the sentiments which should guide Congress in making this appropriation, to foster the successful study in this country of military hygiene, military medicine, and military surgery, for our material interests "as well as the humanitarian sentiments which characterize our modern civilization." He also points out the comparatively trifling cost as a national expenditure of such a library and museum, as almost all other civilized nations have spent much more money in this direction than ourselves, yet the expense is so great as to prevent the establishment of such collections by the resources of individuals or private corporations.

## Miscellaneous.

### REPORT OF THE SEVENTY-SIXTH ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

HELD AT ALBANY, FEBRUARY 7TH, 8TH, AND 9TH.

#### FIRST DAY'S PROCEEDINGS.

THE President of the Society, DR. A. JACOBI, of New York, opened the meeting with his

#### INAUGURAL ADDRESS.

Reviewing the changes that had occurred in the practice of medicine during the life of the Society, he showed that in earlier times it was the practitioner and not the professor who gave the greatest advances to medicine, now, year by year, these two classes were becoming less distinct, and, as their interests become more identical, their services were more valuable. The employment of specialists as instructors had done much to further the reform. He alluded to the universal and constant discussion among the profession at large of measures for the advancement of medical education, and the stimulus these gave to improvement in medical schools. In this connection, deprecating the present system of legislation which permits the matriculants of any school to practice, — although the requirements for a diploma are so lacking in uniformity, he urged the passage of a law which should exclude all unworthy members of the profession, and the appointment of a State Board of Examiners who should grant licenses only to those whose education, both preliminary and medical, entitled them to recognition.

Commenting upon the legislation of 1872 upon this subject, which was inefficient from the introduction of a clause recognizing homœopathy, he spoke in a spirit of very progressive liberality, urging that regular physicians should not be the most backward in promoting harmony, nor should strive to exclude from the expected benefits of the new bill those who share with them the honor of legal recognition. Dismissing the subject of medical education and improvement he discussed next public hygiene, especially with reference to diphtheria and scarlatina, which, as contagious diseases, he declared were constantly disseminated by the practice of congregating cases, and insisted that every patient should be isolated. He showed the present difficulty in the proper treatment of contagious diseases, especially among children, to be lack of suitable institutions, and urged the coöperation of the Society in securing a new hospital for this purpose.

The last topic introduced was a recommendation for more stringent legislation regarding employment of children in factories, and the advocacy of a bill including, as essential points: —

First. Children employed in factories should be under official supervision. In large cities the boards of health could be entrusted with this supervision.

Second. Before being admitted to factory work, a child, of legal age, ought to be examined. Chlorotic, anæmic, scrofulous, crippled, scorbutic, bronchitic, and phthisical children, and those under the normal size of their ages, must be excluded, and the physician's certificate should be conclusive.

Third. No night or Sunday work should be permitted.

Fourth. Some branches of work should be forbidden entirely. There are some which are known to inter-

fere with physical development, and others which are known to prove highly dangerous to childhood and adolescence for various reasons. These are mining, glass-works, rag sorting, employment on mercury, lead, arsenic, iron and brick works, and match factories.

Fifth. The earliest age at which the young ought to be admitted to manufacturing employments, should be fourteen.

In concluding his address the President paid a pleasing compliment to professional liberality and hospitality in America.

DR. F. R. STURGIS, of New York, presented the first regular paper of the day on Hints and Thoughts on Medical Education, referring all the present defects in American medical education to the necessity of conducting nearly all the schools as money-making enterprises on business principles. The reader also insisted on the importance of a State Board of Examiners. The remedies suggested were: —

"First, the absolute incorporation of medical schools with some chartered college or university; make the governing bodies of both the same.

"Second, endow the school liberally for educational purposes and make it independent of its students.

"Third, separate the right to practice from the diploma. This latter, then, should be a token of proficiency in study and knowledge, and its possession from some school in good legal and professional standing should be made obligatory before a candidate can present himself for authority to practice in the State." Dr. Sturgis closed his valuable paper by quoting from the report of President Eliot, of Harvard, the following requisites of a good medical education: "First, that the number of clinical instructors should be as large as the community can well supply; and, secondly, that the University should be more concerned to have a very good school of medicine than a very large one."

DR. E. R. SQUIBB, of New York, followed with a scientific paper on Defective Construction of Thermometers due to various causes.

DR. W. S. ELY, of Rochester, gave some Notes on Beef Juice.

The afternoon session was devoted to papers, among the readers being Drs. SEGUN, C. S. BULL, and VANDERPOEL, of New York.

#### CODE OF ETHICS.

The report of the committee on revising the Code of Ethics was submitted in the evening. The changes were principally the abolition of many antiquated and useless rules, and the encouragement of a more liberal spirit towards practitioners of other schools of medicine, especially in the matter of consultations.

DR. D. B. ST. JOHN ROOSA, of New York, proposed as a substitute for the report of this committee a new code, in which the only ethical offenses for which the medical profession claimed and promised to exercise the right of discipline were those comprehended under the commission of acts unworthy a physician and a gentleman. This substitution, failing to obtain the necessary two-thirds vote, was not adopted.

#### SECOND DAY'S PROCEEDINGS.

Following the business meeting and the reports of committees the day was devoted to scientific papers. Among the more contributors were Drs. AUSTIN FLINT, L. D. BULKLEY, H. D. NOYES, and C. R. AGNEW, of New York.

## THE ANNIVERSARY ADDRESS

was delivered in the evening by the President, Dr. JACOB, of New York, on Infant Feeding and Infant Foods. The statistical part of the paper showed that in New York twenty-eight per cent. of the infant population die during the first year, and forty to fifty per cent. of these from diseases of the digestive organs. Great credit was given the efforts of the Society for the Prevention of Cruelty to Children to lessen this excessive mortality by attention to infants' food. The value of breast milk during the first months of infancy was strongly insisted upon, and disease or absence of milk were the only excuses allowed for neglect on the part of the mother to nurse. The common fault in breast milk was stated to be an undue proportion of fat, casein, and salt, which was easily corrected by attention to diet. Cows' milk was ranked next to breast milk, with the caution that what was popularly called "good" milk contains an excess of fat and consequently was unfit for infantile digestion. Properly dieting the animal and employment of the morning milk diminished this excess of fat. Skim milk was condemned as an article of food for infants. A description was given of the establishments in Europe where cows' milk was pre-

pared for infants' use, showing the great care exercised in the choice of animals, their diet, and the stable accessories.

The ideal article of infants' food was defined as that supplying sufficient material to build up the tissues and promote an equal temperature and normal action of the vital organs. Most of the so-called "Infant Foods" were condemned as failing in these requisites.

## THIRD DAY'S PROCEEDINGS.

The reports of several committees were submitted and ordinary business transacted.

The only papers read were by Drs. D. W. GOODWILLIE and E. H. M. SELL, of New York. A number of papers were presented by their title only.

The form of an amendment to chapter 746 of the Laws of 1872, entitled "An act relating to the examination of candidates for the degree of doctor of medicine," was presented by the committee to which the subject had been referred, and recommitted. The committee also presented the draft of an act to regulate the licensing of physicians and surgeons, the previous laws of 1872, 1880, and 1881 having fallen into abeyance or worked unsatisfactorily. No action was taken. The Society adjourned.

## REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 4, 1882.

| Cities.                           | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |                     |

Deaths reported 2235 (no reports from Brooklyn, Chicago, Cincinnati, New Orleans, Cleveland, and Buffalo); 887 under five years of age; principal "zymotic" diseases (small-pox,

measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 515, consumption 319, lung diseases 343, diphtheria and croup 117, scarlet fever 118, small-

pox 54, measles 39, typhoid fever 56, erysipelas 28, whooping-cough 17, diarrheal diseases 16, malarial fevers 14, cerebro-spinal meningitis nine, puerperal fever eight. From *scarlet fever*, New York 101, Philadelphia seven, St. Louis, and Baltimore three each, Pittsburgh two, District of Columbia and Lynn one each. From *small-pox*, New York 20, Pittsburgh 14, Philadelphia 12, District of Columbia three, Boston, St. Louis, Baltimore, Milwaukee, and Adams one each. From *measles*, New York 35, Philadelphia, St. Louis, Baltimore, and New Bedford one each. From *erysipelas*, Philadelphia 15, New York seven, Baltimore four, St. Louis and Lynn one each. From *whooping-cough*, New York five, Philadelphia, Boston, Baltimore, Pittsburgh, and Attleborough two each, Lynn and Somerville one each. From *diarrheal diseases*, New York 11, Boston and St. Louis two each, Baltimore one. From *malarial fevers*, New York nine, St. Louis and District of Columbia two each, Milwaukee one. From *cerebro-spinal meningitis*, New York two, Philadelphia, Boston, Pittsburgh, Milwaukee, Salem, Holyoke, and Haverhill one each. From *puerperal fever*, District of Columbia and Pittsburgh two each, New York, Boston, St. Louis, and New Haven one each.

Seventy-four cases of small-pox were reported in Pittsburgh, 14 in Baltimore, four in Milwaukee, four in Holyoke, three in Boston, Adams three, and District of Columbia one; diphtheria 23 cases, scarlet fever 15, typhoid fever 10, in Boston; scarlet fever 11, and diphtheria five, in Milwaukee.

In 42 cities and towns of Massachusetts, with a population of

1,090,033 (population of the State 1,783,086), the total death-rate for the week was 20.60, against 23.48 and 19.79 for the previous two weeks.

For the week ending January 14th, in 173 German cities and towns, with an estimated population of 8,275,419, the death-rate was 24.9. Deaths reported 3963: under five 1777; pulmonary consumption 538, acute diseases of the respiratory organs 439, diphtheria and croup 237, diarrheal diseases 117, scarlet fever 92, whooping-cough 68, typhoid fever 52, measles and röteln 35, puerperal fever 23, small-pox (Dresden, Frankfort-on-Oder, Aachen, Eupen two) five, typhus fever (Königsberg, Thorn, Tilsit, Posen) four. The death-rates ranged from 13.4 in Cassel to 41.7 in Kiel; Königsberg 31; Breslau 30.3; Munich 28.9; Dresden 25.3; Leipzig 20.9; Hamburg 25.6; Hanover 27.5; Bremen 20.5; Cologne 30.5; Frankfort 17.8; Strasburg 27.1.

In the 28 English towns, with an estimated population of 8,455,308, for the week ending January 21st, the death-rate was 22.6. Deaths reported 3669: acute diseases of the respiratory organs (London) 417, whooping-cough 178, measles 127, scarlet fever 96, fever 46, diarrheas 42, diphtheria 31, small-pox (London 20) 21. The death-rates ranged from 15.6 in Derby to 33.4 in Oldham; Bristol 30.1; Birmingham 20.6; Leeds 20.6; Manchester 22.2; London 22.8; Liverpool 24.7; Sheffield 25.1. In Edinburgh 18.4; Glasgow 25.4; Dublin 33.7.

The meteorological record for the week ending February 4th, in Boston, was as follows:—

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 4, 1882, TO FEBRUARY 10, 1882.

WOODHULL, A. A., major and surgeon. The leave of absence granted him in S. O. 227, A. G. O., 1881, is extended one month and ten days. S. O. 27, A. G. O., February 3, 1882.

TREMAINE, W. S., captain and assistant surgeon, who reported at these headquarters January 9, 1882, per paragraph 12, S. O., C. S., A. G. O., will await further orders in New York city from date of his so reporting. S. O. 20, Department of the East, February 7, 1882.

WOOD, M. W., captain and assistant surgeon. The seven days' leave granted him on 4th inst. by post commander, Fort Brady, Mich., is extended twenty-three days. S. O. 19, Department of the East, February 6, 1882.

THE SURGICAL SECTION OF SUFFOLK DISTRICT MEDICAL SOCIETY will meet on Saturday, February 18th, at 19 Boylston Place, at eight o'clock. Dr. D. W. Cheever will report A Case of Cæsiophotomomy, with Fatal Results; also A Case of Litholapaxy, Successful. Dr. G. W. Gay will report A Successful Case of Litholapaxy. Dr. Henry J. Bigelow will take part in the discussion. H. C. HAYES, Secretary.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting of the Society will be held on Monday evening, Feb-

ruary 20th, at eight o'clock, at 19 Boylston Place. Reader, Dr. Nichols. Subject, A Case of Abdominal Abscess.

M. H. RICHARDSON, Secretary.

ALBANY MEDICAL COLLEGE.—The annual dinner of the Alumni Association of the above institute will take place at the Delevan House, Wednesday, March 1, 1882, immediately after the commencement exercises at Sneddle Hall.

W. G. TUCKER, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED.—Moral (Affective) Insanity. A Plea for its Retention in Medical Nomenclature. By C. H. Hughes, M. D., St. Louis, Mo. Abstract of Paper presented to London International Congress. (Pamphlet.)

Opium-Smoking in America and China. A Study of its Prevalence and Effects, Immediate and Remote, on the Individual and the Nation. By H. H. Kane, M. D. New York: G. P. Putnam's Sons. 1882.

Transactions of the Thirty-First Annual Meeting of the Illinois State Medical Society, held at Chicago, May 17, 18, 19, 1881.

Transactions of the Minnesota State Medical Society, 1881. Transactions of the Medical Society of the State of New York for the Year 1881.

A Manual and Atlas of Medical Ophthalmoscopy. By W. R. Gowers, M. D., F. R. C. P. Second Edition. Philadelphia: Presley Blakiston. 1882.

## Original Articles.

NOTES ON CASES OF TYPHOID FEVER OCCURRING IN THE SERVICE OF DR. LYMAN AT THE BOSTON CITY HOSPITAL FOR QUARTER ENDING DECEMBER 31, 1881.<sup>1</sup>

DURING the last quarterly term of service, namely, from October to December inclusive, forty-seven cases of typhoid fever came under my charge. Of these, one died, one remained with phthisis complicated with syphilis, and the remainder were either discharged well of the fever or were so far convalescent as to be out of danger. Of the above cases many presented nothing unusual, running an uninterrupted course of greater or less severity to ultimate recovery, but all of them with certain pathognomonic symptoms in addition to the febrile condition, such as enlarged spleen, epistaxis, rose spots, diarrhoea, high temperature, etc., which made the diagnosis clear. Other cases of simple febricula without marked symptoms to justify a diagnosis of typhoid are not included in this summary.

As some of the cases presented interesting features, either during their course or as sequelae, I present them to the Society as a topic for discussion.

The number of cases for the quarter was unusually large. Heretofore admissions with typhoid have rapidly diminished after October 1st, but this year it has been otherwise, new cases being admitted until quite late in the season, a circumstance due, probably, to the unusual atmospheric conditions, the remarkable prolongation of mild autumnal weather. Whether the notorious condition of the city water supply for drinking purposes could have had any influence is uncertain, though the coincidence is noticeable.

Catarrhal and pulmonary complications have been more prominent than usual, in some instances, indeed, soon becoming the most important element of danger from broncho-pneumonia, pleuritis with effusion, and some terminating in well developed phthisis. A few of these I will sketch.

**CASE I.** *Typhoid fever followed by pleuritis and effusion.* James Phalan, twenty-seven years, single, entered September 27th. After a severe attack he convalesced so as to be able to sit up in three weeks, but in a day or two he had a sharp attack of pleuritis with well marked friction rub followed by effusion. This rapidly absorbed and in less than a fortnight he was discharged entirely well.

**CASE II.** *Pleuritis and muscular pains.* Beverly McDonough, age twenty-nine, entered September 21st with well marked symptoms. The disease progressed favorably for three weeks, though characterized by unusual prostration, tympany, and pain. When apparently convalescent he had a sharp attack of pleuritis. The convalescence from this was marked by severe rheumatic pains in the arms and lumbar region. He was discharged well November 14th. The chart shows a long continuance of high temperature with regular typhoidal curve in both primary and secondary affection. For sixteen days, from September 21st to October 7th, his temperature ranged from 103° F. to 104.5° F., fell for a week, and then rose again for ten days from 101.5° F. to 103° F.

**CASE III.** *Typhoid fever followed by pneumonia.* Bertha Roberts, age four, entered August 21st. She was very ill, and upon convalescence, September 18th, broncho-pneumonia developed, from which she recovered after long convalescence, and was discharged November 1st. The chart gives high and irregular temperatures.

**CASE IV.** *Laryngitis and hæmorrhage.* Henry Kolb. Entered September 11th. Had apparently no pulmonary signs, but the course of the disease was attended with a good deal of vomiting, diarrhoea, and delirium. On the fourteenth day he had a slight attack of hæmoptysis. Nothing further of importance occurred until the temperature became normal, on the 2d of October, when he had a well marked attack of laryngitis with cough and aphonia, which continued until November 7th, when he began to regain his voice and was discharged well on the 14th with nothing discoverable in the lungs by auscultation.

Intestinal hæmorrhage occurred in three cases as follows:—

**CASE V.** Garrett Fitzgerald, age thirty, entered December 21st, having been sick for some weeks. He was in a state of delirious stupor with diarrhoea, a black, dry tongue, and a most unpromising condition generally. Spleen much enlarged. On the 26th had an involuntary defecation with a small quantity of blood, followed in a few hours by a profuse and exhausting hæmorrhage, and later in the day a third, smaller in quantity. There was no subsequent recurrence, he convalesced very rapidly, and by January 16th was entirely convalescent.

**CASE VI.** Martin Haley (or Foley) entered August 28th with epistaxis, diarrhoea, etc. His temperature, as shown by the chart, with remissions of three to four degrees between morning and evening, went to 105.2° F. on the 1st and 3d of September, otherwise nothing unusual until the 20th, when he was able to sit up. On the 22d he had a return of diarrhoea with some hæmorrhage, and again on the 24th. Those were supposed to be due to improper food given surreptitiously by his friends. On October 14th he was discharged well.

**CASE VII.** F. Boylan, age 20, single. Entered October 14th, having been sick a week with usual symptoms. On the 18th had epistaxis and abundant rose spots, on the 21st was delirious and had a dichrotic pulse; on the 26th he had a recurrence of the epistaxis with carphologia; on the 28th excessive tympany, and on November 1st a very profuse hæmorrhage from the bowels followed by a smaller hæmorrhage and death.

The skin was affected by unusual symptoms in two cases, and in one case facial erysipelas existed as a complication.

**CASE VIII.** *General erythematous eruption.* Ellen Keefe, age twenty, single. Entered October 3d; besides rose spots there was a general erythematous rash over the arms and legs; there was no syphilitic history. In this case the spleen was enlarged to an unusual degree and very painful on pressure. November 2d three well marked fresh rose spots appeared. The splenic tenderness continued to November 24th.

The 5th of December she was discharged well.

**CASE IX.** *Macule.* John Roach, age thirty-seven, entered November 22d with well developed fever of two week's duration, with much cerebral disturbance, subsultus, spleen enlarged and tender. The trunk and legs were covered with a large number of macule from

<sup>1</sup> Read by Dr. Lyman before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, January 21, 1882.

the size of a pin's head to a split pea. Some of these were crimson, but none resembled the darker macule of typhus. On the 24th began to improve, the charts showing temperature descending rapidly to below normal, the delirium disappeared and convalescence was rapid to December 3d, when he was discharged well.

**CASE X. *Erysipelas, taches bleues.*** William Gil-martin entered November 7th, having been sick one week with headache, sleeplessness, brown, dry tongue, epistaxis, and diarrhœa. On the 10th "taches bleues" were abundant on abdomen and thighs. December 3d, after an increased temperature of several days, quite a sharp attack of facial erysipelas supervened, lasting to December 11th, after which convalescence was rapid and he was discharged well on the 24th. (The chart gives a regular typhoid curve until erysipelas supervened, when the contrast became marked.)

Muscular pains of unusual severity and obstinacy have also been a marked feature, due, presumably, to partial granular degeneration of the muscular fibre from defective nutrition. In one of these, complete paralysis of the lower extremities is noticed as follows:—

**CASE XI. *Typhoid fever followed by temporary paralysis.*** Mary Nyphon, twenty, single, entered September 1st, complaining for a week with pain in the head and bones, and weakness. Has had some cough and diarrhœa, also chancreoid ulcers in vagina. Has been confined to bed for one week. Pulse 126, temperature 104° F.

September 4th, examination of chest gave negative results. Has no symptoms corresponding to the high temperature.

September 7th, vomiting. Mind quite stupid.

September 9th, temperature 105° F., more drowsy and delirious, rose spots and diarrhœa.

September 14th, abundant sonorous and sibilant râles, temperature 105° F., and very delirious.

September 18th, mind clear, but answers slowly; much prostrated.

September 22d, delirious again, and more prostrated. She was desperately ill for a few days, rejecting everything from stomach.

September 30th, mind became clear though with rising temperature, tongue more moist. She continued with alternations of diarrhœa, vomiting, etc., to October 8th, when she again became delirious and deaf.

October 10th, was better. The râles disappeared, the chancreoids healed, and she improved slowly but steadily, with normal temperature, to the 31st, when she was allowed to get up. On attempting to walk found an entire loss of power in lower limbs. She could stand with assistance but was unable to control the direction of her movements. Under the use of frictions, stimulants, and good diet she gradually regained locomotive power and was discharged well November 18th.

In this case the temperature ranged from 101° F. to 105° F. to the sixteenth day after entrance, then gradually receded to 99° F. the twenty-second day, when it began to rise again to the 28th, the thirty-third day of her illness, when it reached 104.6° F. From this it fell gradually to normal.<sup>1</sup>

One case was noticeable as being followed, when entirely convalescent, by a sharp attack of variola, and is merely mentioned here, not as having any relation to the antecedent fever, but as showing the occasional difficulty of tracing the origin of contagious disease. The patient entered the hospital October 22d, on the tenth day of typhoid fever. It pursued a regular course. She was convalescent November 18th, up and about the ward. On the 21st she was attacked with nausea, lumbar pains, injected conjunctivæ, etc., temperature rising to 105° F., and pulse 124. On the 22d the vesicles were manifest, and she was transferred to Small-pox Hospital, where she eventually recovered. She had had no exposure to outside contact for a month. It can only be accounted for by supposing that the germs had been implanted before entrance, remaining latent during the intercurrent typhoid.

Finally, three cases of well-marked phlebitis or thrombosis occurred as sequelæ to the fever, and I may add that a fourth occurred in my private practice about the same time, a sketch of which I shall add to the others. The first of these was so slight a case as to be hardly worthy of notice, except as in connection with the others.

**CASE XII. A. M., twenty-one, single, entered September 3d.** He had a severe attack, with rose spots, delirium, subsultus, etc. The fourth day after entrance his chart records a temperature of 105.5° F. From that time it fell steadily, reaching normal on the 16th of September, the nineteenth day of the disease. He remained in the hospital for convalescence until October 15th, when he had pains in the right leg and ham, with œdema. The application of a blister, with flannel bandaging, relieved the pain, the œdema gradually subsided, and he was discharged well October 26th.

**CASE XIII. D. McD., aged twenty-eight, entered December 17th, convalescent from typhoid of six weeks' duration.** He had three rigors before entrance, night sweats for a week, and was very anæmic, tongue dry and brown, and he complained much of pain in the right leg, which was swollen and œdematous. This pain, first noticed in the calf, was now chiefly in the foot, the inner aspect of the thighs, and about the crural opening, where it was tender on pressure. A blister was applied to the groin, the leg firmly bandaged, and tinct. chlo. iron given internally. The relief to the pain was immediate, the tenderness and swelling gradually disappeared, and he was discharged well January 7th with some weakness only in the limb.

**CASE XIV. B. S., twenty-nine, entered November 5th with well marked symptoms.** Temperature 105° F.; daily typhoid dejections, tympany, stupor; dielrotic pulse; subsultus; a few bronchial râles; and much prostration. His temperature after the first day was very irregular, varying from 99° F. to 103.5° F., with the ordinary course of a grave case of typhoid until the 27th, when he had a marked rigor, followed on the 29th by one still more severe, the temperature rising to 105.6° F. On seeing him the following morning I found well marked bronchial respiration, with flatness on percussion over the lower right back, and above the nipple in front, with a few moist râles on forced respiration. His evening temperature fell to 97° F., eight and six tenths degrees; pulse 76. On the following day, December 1st, in addition to the pulmonary complication there appeared swelling and œdem of the left leg and thigh, but without pain,

<sup>1</sup> A case of purpural polyæthærosis of long duration, but now convalescent, was mentioned in this connection, where the loss of sensation and motion in lower extremities is well marked. Her chart shows long continuance of high temperature.

heat, or redness. Patient very stupid. December 2d. Limb more swollen, and notwithstanding his weakness and stupor he complained manifestly of pain and tenderness in the popliteal region. On the 6th he had another severe rigor, and on the 8th there was discovered hardness and pain in the femoral region, with extensive œdema from the toes to the groin. These were relieved by a blister and a firm flannel bandage from the foot upwards. From this date he rapidly convalesced from his complicated troubles, and was discharged well January 10th, with but little weakness remaining in the limb.

CASE XV. Mrs. F., aged sixty, was taken the 1st of November with the ordinary symptoms of mild typhoid. She complained mostly of headache and extreme prostration, and there was occasionally some mental confusion. The temperature on two occasions only, rose above 100° F., once to 103.2° F., and once to 100.5° F. The disease ran its course with no complications until the commencement of convalescence, early in December, when she had a sharp attack of pneumonia, with pain, chill, and dyspnoea. She had crepitant râles, succeeded by bronchial respiration and gradual resolution. The worst day of the disease was December 9th, when her temperature was 101.5° F., pulse 140, respiration 42. The pain prevented cough and expectoration, but there was a constant subdued effort at cough. The bed-pan being very troublesome in the horizontal position, she, on several occasions, rose from the bed to use it, but the tendency to syncope, once resulting in momentary loss of consciousness, was so marked that she was forbidden to repeat the experiment. December 16th I considered her convalescent, but the following day she complained of swelling, pain, and stiffness in the right leg, with a renewal of febrile symptoms. The swelling of the limb rapidly assumed enormous proportions. A blister to the upper part of the thigh, with tight bandaging from the foot upwards, relieved her discomfort, and now, January 21st, the swelling is nearly gone, and she is able to walk from room to room. I should add that Mrs. F. has for some years had more or less of inconvenience from varix of both lower extremities.

It is quite common to call such cases of venous obstruction, with more or less of hardness and tenderness of the veins, and with distal swelling and œdema, phlebitis, but it is questionable whether this is not without sufficiently careful discrimination between phlebitis and thrombosis.

We may have phlebitis of the crural, for instance, with thrombus as one of its results, or thrombus may occur as the result of weakened circulation and altered blood, followed by more or less phlebitis, as is evidenced by the pain, tenderness, and febrile reaction.

A partial anasarca may well enough occur in typhoid fever from cardiac weakness, renal complication, or enlargement of mesenteric glands, all of such common occurrence in typhoid, but true thrombosis and much more true phlebitis is probably not of frequent occurrence.

Liebermeister gives<sup>1</sup> but thirty-one cases of thrombi in 1743 patients, and Dr. DaCosta, in a recent number of our Medical and Surgical Journal, cites such a case as a rare and unusual complication.

A simple thrombus occurring, as is usually the case, late in the disease, should be of itself rarely fatal, and the less so the more distant from the heart, but it

should lead to extra caution until the convalescence is unmistakably well advanced; and until the heart has recovered its tone, common prudence dictates absolute rest and freedom from excitement. If it be the expression of cardiac weakness from muscular degeneration, the erect posture, by inducing faintness (as in the last of the above cases), might result in heart clot. Or too early exertion may favor the formation of an embolus from detachment of a portion of the clot. This is now well recognized as a matter of importance in all exhausting diseases complicated with high temperatures.

Entire rest, proper bandaging of the swollen limb, and, if there be local tenderness discoverable, a small blister, will usually give great and speedy relief. The above cases, it will be noticed, all occurred so late in the disease that a blister was unobjectionable.

I offer the above cases chiefly as being illustrations of the well-known tendency existing after exhausting disease with long continued high temperature, to granular muscular degeneration, and also to the liability to fibrinous deposit in any septic condition of the blood, causing thrombi either in the larger vessels of the extremities, where they are immediately recognizable, or in the capillaries of the internal organs, lungs, liver, spleen, and kidneys.

#### A CASE OF DISEASE OF THE LIVER TERMINATING FATAALLY IN A MONTH.<sup>2</sup>

BY HENRY J. BIGELOW, M. D.

I HAVE been requested to report this medical case here to-night. The patient was about forty years old, and had been in good health up to the early part of November, 1881. He possessed a robust constitution, and his antecedents were healthy. When a child he had been subject to prolonged attacks of pain in the bowels, the character of which it is not easy now to determine, but for which he was subjected to a severe dietetic regimen for many weeks at a time; evidence, perhaps, connected with the condition of the appendix caeci discovered at the autopsy. He spent the summer of 1881 at his country residence, and was then in excellent health.

On the 1st of November he returned to town, when certain prodromata at once supervened. These symptoms were mainly a feeling of weariness, with loss of appetite and sleeplessness.

November 14th the patient had a first and only chill, followed by pain in the bowels, for which he took a dose of oil without relief. The next day, November 15th, Dr. Bigelow saw him. There was then a localized pain in the region of the anterior superior spinous process of the right side, with tenderness on pressure to a degree that suggested the existence of typhilitis or perityphilitis. This pain lasted three days, and, November 20th, was replaced by another. The location of the second pain was three inches higher on the abdomen, with less tenderness, being more like colic, and was treated with opiates in small doses. This continued a few days, and then in its turn also subsided.

On the 23d of November a pain began to locate itself near the lower border of the ribs, being indistinctly diffused over the entire hepatic region. There was now

<sup>2</sup> Reported to the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, January 21, 1882.

<sup>1</sup> Ziemssen, vol. i., 164.

also dyspnoea and shortness of breath, directing attention to the thorax, which was repeatedly and carefully examined. But although a certain feebleness of respiration and dullness existed at the lower part, it was soon determined that this was not due to pleurisy. The dyspnoea was the result of pain in the hepatic region. The tenderness now extended quite around this side of the chest.

About December 1st there was a little oedema, the skin being now pitted upon pressure over the side and back.

Dr. Bigelow here read a passage from Ziemssen,<sup>1</sup> which had suggested to him at this time what proved to be the correct solution of the various symptoms in this case, namely, an inflammation near the head of the caecum extending through the venous circulation to the liver, spreading and suppurating in that organ. The principal symptoms were now (early in December) those of inflammation of the liver. There was little doubt of suppuration in or about the liver; for though the absence of chills was thought remarkable, authorities agree that chills are not necessarily present in suppuration of the liver. The liver now began to appear in the right hypocondrium; a portion measuring one finger long by two fingers broad protruding below the margin of the ribs. This part alone was accessible to the touch, and to this the patient referred a chief pain and tenderness which continued till the end. Death occurred December 14th, a month after the invasion of active symptoms.

The charts of temperature and pulse in this case are interesting by their negative indications. From November 16th to November 23d the temperature was normal. November 24th and 25th it reached its highest point, being 101.5° F. December 1st, 2d, and 3d it was never higher than 101° F., and in the afternoon sank regularly to about 99° F. From this time the temperature was nearly normal, and during the remainder of the disease was often a degree below that point. The pulse stood at about 70 during the entire illness till three days before the fatal termination, when it gradually rose to 100, its highest rate. The tongue was uniformly covered by a light-colored pasty coat, not dry until a few days before the fatal termination. The bowels were constipated, but the daily employment of opiates to alleviate the pain may have contributed to this result. During the last week of the disease there were two large evacuations of dark color and pasty consistence, each discharge followed by an alarming exhaustion and collapse. These unfortunately were not analyzed. They possibly contained blood. If so the hæmorrhage was not a recent one. The anorexia was complete throughout the disease, food consisting of arrowroot and broth being taken with reluctance. There was never vomiting. During the third week of the disease the oedema of the right side became more marked, and there was anasarca of the right leg and foot. As the oedema of the side increased the patient was examined daily to determine the possibility of aspiration. There was no indication to justify this operation. The autopsy showed that any attempt at aspiration would have been fruitless. There was a slight jaundice of the conjunctiva during the last three days. The urine was scanty, but was not examined chemically or microscopically during the disease. Before death the abdomen was tympanitic and tender, as it might be from peritonitis.

In consultation Dr. Wyman saw the patient repeatedly, and at a final consideration of the question of tapping, also Dr. Hodges.

## A PARTIAL REVIEW OF EIGHTEEN CASES OF GENERAL PARALYSIS OF THE INSANE.<sup>2</sup>

BY E. S. BOLAND, M. D.

I HAVE to offer to-night only an imperfect review of eighteen cases of general paralysis, which are among those treated at the Boston Lunatic Hospital since April, 1878.

Four of these cases still live, and have to be excluded from some of the figures.

From incomplete records and want of systematic observation some important clinical facts have been overlooked. This paper was first thought of as a consideration of the epileptiform seizures of general paralysis, but my facts were found to be too scanty to be of value. The same is true of the patellar and pupillary reflexes and ophthalmoscopic examinations to some extent, these latter having been noted only in the last half of the cases.

I have no new facts nor theories to advance as to cause, pathology, or treatment, but trust that the interchange of opinion which this reading may occasion shall be of mutual benefit.

This investigation has shown me the necessity for a systematic form for case taking and recording, so as to be of value for study and comparison. The following facts in regard to these eighteen cases are arranged according to such a form.

For the time covered by this paper the general paralyties were ten per cent. of all admissions.

*Sex.*—One female, seventeen males.

*Age.*—The ages on commitment varied from thirty to sixty-eight years, average forty-five and one third years.

*Nativity.*—Twelve American; three Scotch; one English; one Holland; one New Brunswick.

*It is seen there are no Irish in this list, though the actual number of Irish is over twenty-seven per cent. of all admissions. The exemption of the Irish has been discussed by English observers, but I do not remember to have seen a satisfactory explanation.*

*Occupation.*—Five worked at trades; four merchants; four clerks; three worked at mechanic arts; two followed professions.

The number following laborious occupations is seen to be small.

*Social condition.*—One widower; three single; fourteen married.

*Hereditary predisposition.*—Two known to have had insane relatives; sixteen either no hereditary influences or antecedents unknown.

*Habits as to the use of alcoholics.*—Three were known to have been intemperate; three were known to have been moderate drinkers; twelve were known to have been temperate.

*Sexual habits.*—Three were known to be addicted to excesses. One showed increased sexual desire after the inception of the disease. Three had other venereal troubles, as stricture, gleet, suppurating bubo or scars. Three only were believed to have had syphilis.

<sup>1</sup> Vol. xix., pages 899-917.

<sup>2</sup> Read before the Boston Medico-Psychological Society.

**Epileptiform seizures.**—Ten had the seizures from three months to as many years before death. Six had the attacks from two to twenty days before death. Two have not yet had the seizures.

Many of the attacks could not be distinguished from the *grande mal*, except that the sphincters were more often involved, and the temperature was almost always found increased during and after the attack, and ranged from 99° to 105° F., the latter with a fatal termination.

**Gait.**—Ten showed ataxic gait on admission. In the other cases ataxia did not occur until months later, and in one case the patient could run as late as two days before he died.

**Appearance.**—In three depression was observed. The others were either maniacal, exhilarated, or vacantly contented.

**Speech.**—Ten, speech much affected on admission. Four showed but little impairment until the onset of the fatal convulsions. Four seemed to be cases of ataxic aphasia, for there was no lack of ideas or of will to express them.

**Nature of the ideas or delusions.**—Twelve had the expansive delirium in regard to their abilities, prospects, or possessions. Six showed no such extravagant ideas.

**State of the eyes.**—Dilatation of pupils not noted. Contraction of pupils seen occasionally. Inequality of pupils noted often after the epileptiform seizures. In two the mobility of the eyes (ocular muscles) was so great as to interfere with the examination. Nine cases examined with the ophthalmoscope gave negative results.

**State of patellar reflex.**—Thirteen were tested as to the knee phenomenon. Eleven gave the normal reaction; one gave no reaction; one gave the rebound on the right side, but not on the left.

**Length of Disease.**—Average time in hospital, twenty-two months. Average time of disease thirty-seven months.

**Mode of death.**—Gradual exhaustion associated with hypostatic pneumonia, oedema of the lungs, inhalation pneumonia, and bed-sores. After the epileptiform seizures bed-sores would often form, to heal again after the effects of the seizure had passed off.

**Pathology.**—Of fourteen dying in the hospital twelve were examined, seven by the staff and five by Dr. W. W. Gannett and the staff.

The subjoined list shows the principal lesions noted, though the connection or dependence of the clinical observations could not always be demonstrated:—

|  |    |
|--|----|
| Increased thickness of skull . . . . .                               | 4  |
| Abnormally adherent dura . . . . .                                   | 3  |
| Pachymeningitis . . . . .  | 4  |
| Meningeal hæmorrhage . . . . .                                       | 2  |
| Bone plates in dura . . . . .  | 2  |
| Thickening and opacity of the pia . . . . .                          | 3  |
| Degenerative changes in the arteries of the base . . . . .           | 6  |
| Occlusion of one vertebral artery . . . . .                          | 3  |
| Decortication of the summits of some of the convolutions . . . . .   | 3  |
| Atrophy of the brain . . . . .                                       | 14 |
| Oedema of the pia . . . . .  | 14 |
| Gross atrophy of gray matter . . . . .                               | 3  |
| Increase of fluid in ventricles . . . . .                            | 6  |
| Cysts of the choroid plexus . . . . .                                | 3  |
| Granular ependymitis . . . . .                                       | 6  |

## REPORT ON PROGRESS IN THE TREATMENT OF THORACIC DISEASES.<sup>1</sup>

BY F. L. KNIGHT, M. D.

### TREATMENT OF INTRA-THORACIC SUPPURATING HYDATID BY INCISION AND EXTRACTION OF THE CYST. (*Continued*.)

Drs. Fenger and Hollister have a very interesting and exhaustive paper<sup>2</sup> on opening and draining cavities in the lungs, in which they give a case of their own which has also been published in the *Chicago Medical Review*, vol. iii., No. 3. In this case there was, in a man thirty-four years old, a large fetid abscess-cavity in the middle lobe of the right lung caused by supuration around a large echinococcus cyst of twelve years' standing. There was diffuse purulent bronchitis in the rest of the right lung, with fever, emaciation, and collapse. After exploratory aspiration an incision was made in the third intercostal space on the anterior surface, two inches to the right of sternum. Digital exploration of the cavity was made. A counter-opening also was made in the fifth intercostal space, anterior axillary line. The sac of the echinococcus cyst was removed through the anterior opening. Drainage was established by means of a large rubber tube, the cavity was washed out with carbolic acid solution, and antiseptic dressings applied. The fetor of breath and expectoration ceased, and the wound closed in six weeks. In the seventh week there was broncho-pneumonia of the right lung, with diffuse purulent bronchitis of this and of the lower lobe of the left lung, lasting four weeks. There was, however, perfect recovery.

### ÆTIOLOGY OF MILIARY TUBERCULOSIS.

Klein contributes an interesting article on this subject.<sup>3</sup> He says that the evidence afforded by modern pathology favors the assumption that miliary tuberculosis is a specific infectious disease. (Miliary tuberculosis is considered here as defined by Virchow, and altogether distinct from caseous inflammation and scrofula.) This evidence is, however, not yet so complete as we could wish, nor such as to place it on a level with that by which the nature of other specific diseases is already ascertained.

The evidence which has yet been obtained may be conveniently stated under the following heads:—

- (1.) Evidence to show that miliary tuberculosis is communicable from one human being to another.
- (2.) That it is communicable from a human being to an animal, and from animal to animal.
- (3.) Evidence regarding the nature of the *materies morbi*.

He now takes up these heads and considers them in detail:—

- (1.) Evidence that tuberculosis is communicable from one human being to another.

(a.) Tuberculosis may be inherited. Although inheritance is not a distinguishing character of infectious diseases,—being an endowment common to all living matter, and being specially noticeable in certain morbid states altogether distinct from infectious diseases, for example, cerebral abnormalities, cancer, gout, etc., are notoriously capable of being inherited—yet associated with other characters distinguishing a specific dis-

<sup>1</sup> Concluded from page 159.

<sup>2</sup> American Journal of the Medical Sciences, October, 1881.

<sup>3</sup> Practitioner, vol. xxvii., No. II.

ease, inheritance has nevertheless a certain value, even if only an indirect one.

(h.) Tuberculosis is acquired in various ways:—

Firstly, it may be communicated from husband to wife, or *vice versa*. The evidence on this point is rather conflicting, inasmuch as there are a good many assertions denying such a communicability; but as in other conditions, so also here, one well authenticated, positive case outweighs all the negative ones. While Gabler, Drysdale, Guérin, Bouley, and Villemin cite cases to show the communicability of tuberculosis from husband to wife and *vice versa*, Cotton, Pidoux, Roche, and others deny such communicability. Guérin mentions the case of a man who, suffering from tuberculosis, infected his wife with this disease; the man dies and his widow marries again. She, having communicated the disease to her second husband, died; this man marries again, and communicates the malady to his second wife.

Reich observed in the village of Neuenburg, situated on a high bluff of the Rhine, and enjoying excellent hygienic conditions from July 11, 1875, to September 29, 1876, ten deaths from tubercular meningitis in children born between April 4, 1875, and May 10, 1876. No hereditary disposition could be established. All these children were attended by the same midwife, who was suffering from lung disease (caseous and sanguipurulent sputa) and died July 23, 1876. She had the bad habit when the child was born of removing the phlegm from the respiratory passages by sucking with her mouth, and in slight cases of asphyxia, of blowing air into the child's mouth.

(2.) Evidence that tuberculosis is communicable from man to animals, and from animal to animal.

Villemin in 1865 first succeeded in inoculating rabbits with matter taken from human gray as well as softened tubercles and producing in them a disease, which in its general characters showed a great resemblance to disseminated milary tuberculosis, chiefly in the lungs, but also in the liver and intestines, and occasionally also in the spleen.

These experiments of Villemin, that is, of inoculating animals, chiefly rabbits and guinea-pigs, have been successfully repeated over and over again by a great many observers, — Taubhaus, Bijen, Hérard, Cornil, Lebert, Marcet, Hoffmann, Waldenburg, Klebs, Sanderson, and Simon, Wilson, Fox, Cohnheim, and Fränkel, Friedländer, Herring, and many others.

This question of the production of disseminated tuberculosis in animals by inoculation has, in more recent times, assumed altogether a more satisfactory aspect since Cohnheim and Salomonsen succeeded in producing undoubted milary tuberculosis of the iris, with subsequent general tuberculosis, in rabbits and guinea-pigs, into whose anterior eye-chamber a minute particle of human tubercular matter had been previously introduced. The results of these inoculations are so striking and so conclusive that all doubts must disappear as to the inoculability of human tuberculosis into animals to the full extent asserted by Villemin. These assertions, namely, "that human tuberculosis is an infectious disease caused by a specific agent, transmissible to animals," at first, with few exceptions, met with considerable opposition. Compare Pilon, Colin, Aufrecht. But since the last experiments of Cohnheim and Salomonsen, and others presently to be mentioned, they certainly are borne out to their full extent. These observers introduce a perfectly fresh bit of tu-

berculous tissue from the human subject into the anterior chamber of the eye of a rabbit or guinea-pig. They find that in a short time the first irritation passes off, the bit of tissue diminishes gradually in size, and disappears altogether. After the lapse of an incubation period of three weeks there appears suddenly a crop of minute gray tubercles in the iris, which, after having increased to a certain extent in size, undergo cessation.

These observers have been further able to ascertain that this result, namely, an irruption after a definite incubation of minute gray tubercles in the iris, is followed only and exclusively after the introduction of real tubercular matter, and of no other substance. Cohnheim, in his classical work on Tuberculosis (*Ordinarius Medicorum Lipsiensis decanus et reliqui professores memoriam E. G. Boscii, die 23 September, 1879, etc.*), in consequence of this important discovery, borne out by subsequent investigation, is enabled to assert that "To tuberculosis belongs everything which by transmission on suitable animals produces tuberculosis, and nothing, which is not transmissible."

Now, for the first time, we appear to have succeeded in obtaining, through Cohnheim and Salomonsen, the means by which real tubercular matter can be distinguished from all other caseous, secondary, and chronic inflammatory products, especially scrofula, namely, the iris tuberculosis produced in rabbits and guinea-pigs by human tubercle and nothing else.

Besides the transmission from man to man by inoculation, there are recorded observations as to the transmissibility of tuberculosis by feeding. Jacobs mentions that a dog that swallowed for some considerable period the sputa of his tuberculous master showed on post-mortem examination tuberculosis of the lungs and of the pleura.

(3.) Evidence as regards the nature of the *materies morbi*. Brühl was the first to maintain a causal relation between caseous matter and milary tuberculosis, inasmuch as he regards milary tuberculosis as a specific infectious disease due to the absorption of matter from a caseous focus. This dependence of milary tuberculosis on caseous matter received a great deal of support from the production by inoculation with caseous (tubercular and non-tubercular) matter, and with indifferent substances leading to caseous inflammation, in rabbits and guinea-pigs, of artificial milary tuberculosis, or what resembles it. But, as was subsequently proved by Cohnheim and Salomonsen, and by Baumgarten, for the production of milary tuberculosis of the iris with subsequent general tuberculosis in rabbits (compare also Tappeiner's inhalation tuberculosis in dogs) real tubercles (gray or caseous) must be employed, other non-tubercular matter, caseous or catarrhal, not producing any effect. It follows, then, that the *materies morbi* is present in the gray tubercle, and is not present in all and every caseous matter, but only in that derived from real tubercles.

— The *Boston Journal* is responsible for the following: The Board of Health of Arcade, N. Y., has served notice on a farmer living near that village to wash himself. He has not done so, it is claimed, for forty years, and so filthy had he become that a committee was appointed to abate the nuisance if possible.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY: SECTION FOR CLINICAL MEDICINE AND PATHOLOGY.

ALBERT N. BLODGETT, M. D., SECRETARY.

JANUARY 21, 1882. The meeting was called to order at eight o'clock. The death of Dr. T. B. Curtis, who was elected to the office of chairman of the Section at the last meeting, made the election of a new chairman necessary. On motion of Dr. G. H. Lyman Dr. G. B. SHATTUCK was elected chairman. The records of the last meeting were read and approved.

Dr. G. H. LYMAN read a paper entitled

#### SOME OF THE SEQUELÆ OF TYPHOID FEVER.<sup>1</sup>

Dr. BOWDITCH called attention to one of the cases mentioned by Dr. Lyman in which simultaneously with an attack of intercurrent erysipelas there was a notable fall of temperature, and asked the explanation of so unexpected an occurrence. Dr. Bowditch would have expected an elevation of the former temperature, but there was in this case a decided reduction.

Dr. LYMAN said such an event was not common and he attributed it to weakness.

Dr. E. G. CUTLER stated that in the case of one patient with typhoid, there was an intercurrent attack of pleuritis with decided elevation of the former temperature, and in this condition quinine seemed powerless to effect a reduction of temperature. Dr. Cutler also called attention to one of Dr. Lyman's cases, Bertha Roberts, in which the daily fluctuations were extreme and not in accordance with the general variation in this disease.

Dr. LYMAN said that this patient had been a long time in the hospital and was already convalescent from typhoid, and that these temperatures belonged to the sequelæ. In many cases the typical typhoid chart, as described by Wunderlich, is observed, but in the majority the temperature is irregular. Many of the charts show the long continuance of high temperatures as influencing the development of thrombus and the granular degeneration of muscles.

Dr. H. J. BARNES asked if typhoid had not been unusually prevalent this year.

Dr. LYMAN said it had been. Dr. Rowe had endeavored to discover some localization in regard to the various portions of the city, but was unable to do so.

Dr. BARNES observed that people on the Back Bay district of Boston do not suffer from typhoid and that they have not drunk the water supplied to the city.

Dr. LYMAN agreed with the last speaker in the extreme rarity of typhoid on the Back Bay.

Dr. TARBELL gave a brief *résumé* of the cases occurring under his care in the wards of the Massachusetts General Hospital during September and October, 1881.

There were twenty-eight in all. Of these five died and the rest have recovered. Of the complications referred to, five had extreme deafness, three had severe intestinal hemorrhage, three had phlebitis of femoral vein, three had broncho-pneumonia, and four had distinct relapses of the fever. The epidemic of this year had been of an unusually severe type, as indicated by the large death-ratio. Of the five deaths, two were moribund at time of admission, two died in the fourth and fifth week of the fever, after severe intestinal hæm-

orrhages. The treatment consisted of sponging with tepid water, milk diet, with beef tea as a stimulant where it was well borne. Little or no medicine, and alcoholic stimulants to but a small proportion of the patients, and to them only in the period of exhaustion, usually during and after the third week of the disease.

Dr. LYMAN said his treatment was to let them alone, responding only to special indications. Sponging with cool water is employed in cases of high temperature, enemata are administered when constipation is present, at times turpentine stupes are employed, but as a rule they receive no medication whatever. They are given milk in any desired quantity, and stimulants are added if there is cardiac weakness. In some cases a large amount of stimulants is required, and as much as eighteen or twenty ounces are necessary in the course of a day.

Dr. TARBELL recalled a paper read by Dr. Edes some years ago advocating the employment of the cold douche in pyrexia. During the same year Dr. Tarbell had the same number of cases of typhoid in none of which the douche was employed in treatment, and obtained a trifling better result in recoveries.

Dr. LYMAN said he never uses cold baths, and is inclined to think there is much fallacy in this mode of treatment. Dr. Lyman basis his treatment of typhoid on the formula of Thomas Watson, which is to "obviate the tendency to death." Hemorrhage, diarrhoea, etc., must be met by appropriate remedies when necessary.

Dr. HAROLD WILLIAMS said he had recently treated a case of typhoid in which death occurred from phlebitis.

Dr. TARBELL had seen no fatal result from this cause.

Dr. LYMAN said that one of Dr. Sumner's patients in the City Hospital died from phlebitis.

Dr. C. F. FOLSON said that there had been an increase in the prevalence of typhoid fever throughout the State during the year 1881, as well as in Boston. The decrease from 1872 to 1879 had been steady and very great, reaching the lowest death-rate from that cause ever recorded in Massachusetts, at the same time that there was an excessive amount of intermittent fever in the western part of the State, which gradually increased from 1879 to 1880. Typhoid fever had been increasing since 1877. Thus far, it has been the case that, in spite of a great improvement in the sanitary condition of towns from year to year, typhoid fever does not progressively diminish in its degree of prevalence but increases for a period of years, decreases, and then rises and falls in the mortality list as it did before attempts were made to control it. From 1877 to 1880 both typhoid fever and intermittent fever increased in prevalence; from 1880 to 1881, the same has been true of typhoid fever but the opposite of intermittent fever.

Dr. LYMAN asked for information in relation to the correspondence of continued high temperature with degeneration of muscular structures, especially the heart.

Dr. FITZ replied that muscular degeneration takes place independently of high temperatures. Blood poisoning and other destructive processes have a greater influence on granular degeneration of muscular fibre than the temperature. A peculiar waxy degeneration affects the rectus abdominis muscle especially and is often due to hemorrhage into the muscular structure. Muscular degeneration is always associated with great prostration, in which condition hemorrhages may more frequently occur.

Dr. LYMAN said it was interesting to notice how

<sup>1</sup> See page 169 of this JOURNAL.

few cases of muscular degeneration had been observed in the combined cases of Dr. Tarbell and himself. In these seventy-eight cases there was almost entire absence of this feature. In hospital practice it was not probable that the lesion would be overlooked, so that it is fair to consider it absent. This makes it evident that the muscular degenerations must depend upon something else than high temperature.

DR. F. G. MORRILL asked in what proportion of cases a reduction of the temperature is observed after the administration of quinine.

DR. LYMAN replied that it was noticed in almost every instance. The drug was given at night in doses of fifteen to twenty grains and the temperature was uniformly lowered. It is the rule in the City Hospital.

DR. MORRILL observed that in one of the clinical charts the temperature continued high, although quinine was administered.

DR. LYMAN remarked that this was a complicated case, and was not a fair one in which to test the efficacy of antipyretic measures.

DR. MINOT said that in many cases in which twelve grains of quinine effect no reduction of temperature he is accustomed to prescribe ten grains every fifteen minutes until forty grains have been taken, unless the temperature falls sooner.

DR. LYMAN said he followed the same rule whenever the temperature reached  $104^{\circ}$  to  $105^{\circ}$  F. He has observed no ill effects from these large doses. In the City Hospital ten grains is given every hour in excessive degrees of temperature, and in one case ninety grains were administered in one night before the thermometer indicated a lower temperature. He should pursue the same treatment in a similar case. Quinine does not cause deafness in single large doses. In continued small doses deafness often follows.

DR. BOWDITCH called attention to a paper by Dr. Baldwin (of South Carolina?), who contends that quinine often produces great injury to the system, sometimes causing death, and asked the opinion of other gentlemen.

DR. LYMAN replied that the article in question was a part of a controversy in which Dr. Baldwin was engaged with another practitioner in regard to quinine. Dr. Baldwin opposed the reckless administration of quinine for *everything*, as is often the case in the South, but did not object to any proper and necessary use of the drug.

DR. WOOLDRIDGE has long practiced in malarial districts, and has been accustomed to prescribe fifteen to twenty grains at a single dose, and no more. He has usually observed no ill effects, though patients differ in toleration of large amounts of this drug. Some cannot tolerate even small doses without great suffering, and many may have been killed by its continued use.

DR. LYMAN asked if the bromides were given in conjunction with quinine.

DR. WOOLDRIDGE replied that he usually combined them, as the toleration of quinine was thereby augmented, and the bromide is useful in itself.

DR. SHATTUCK observed that numerous cases are reported in German literature in which thirty to forty grains produce delirium and serious gastric symptoms, and that salicin is sometimes substituted for quinine. It is generally administered in cachets. Dr. Shattuck asked Dr. Folsom the relation of intermittent fever to typhoid as shown by the late vital statistics of Massachusetts.

DR. FOLSOM replied that in Berkshire County, dur-

ing the years 1874 to 1876, 1878 and 1879, during an uninterrupted diminution of typhoid fever, intermittent fever increased astonishingly. During 1879-80 both diseases prevailed extensively. It is probable that during the years 1880-81 there has been a decadence of both diseases, but statistics upon this subject are not yet accessible.

DR. H. J. BIGELOW then presented a paper entitled

#### A CASE OF DISEASE OF THE LIVER TERMINATING FATALLY IN A MONTH,

which is published on page 171 of this journal.

DR. FITZ gave an account of the autopsy, which was made about thirty hours after death.

The thoracic organs showed nothing abnormal. On opening the abdominal cavity, gas escaped, the intestines were found glued together by soft, yellow, friable adhesions, and the general peritoneal surface was injected. The right lobe of the liver projected an inch and a half below the costal cartilages, and the diaphragm was displaced upwards to a considerable extent. The transverse colon was adherent to the anterior surface of the liver by recent though moderately firm adhesions, and the anterior surface of the right lobe of the liver was adherent to the edges of the costal cartilages, thus shutting off the portion of the abdominal cavity between the diaphragm and the liver. The cavity thus circumscribed communicated with an abscess extending into the substance of the right lobe of the liver, which, with its wall and contents, represented fully one fourth of the volume of this lobe.

The skin over the lower costal cartilages of the right side was oedematous, and the upper insertions of the external oblique muscle showed a limited but diffused purulent infiltration.

The liver was found to be greatly enlarged and to contain two abscesses. One, already referred to, was in the right lobe; another, wholly disconnected, with a cavity as large as a fig, was in the left lobe, near the surface. The wall of the latter was formed in part by the anterior wall of the oesophageal end of the stomach.

The larger abscess had an irregularly elongated and sinuous cavity. The walls of both were shreddy, and extended outwards into the substance of the liver, for a considerable distance, as lobulated, somewhat arborescent patches and confluent spots. These patches were of a uniform yellow color, and consisted of enlarged and opaque lobules, gradually shading into more reddish-gray lobules of unusual size. The liver in general was paler and more opaque than normal. The examination of the trunk of the portal vein showed nothing abnormal within or around the wall. On opening the branches within the liver, in the immediate vicinity of the large abscess, a soft, curd-like puriform mass was found partly adherent to the wall. The fibrous wall of the vein gradually disappeared, and the canal became wider, with a predominance of the curd-like mass, which represented in part disintegrating liver substance. The examination of the hepatic veins in the immediate vicinity of the abscess showed a somewhat similar condition. In a primary branch of the main vein was a continued thrombus, yellow, conical, not completely filling the vessel, the centre of which was in a state of yellow softening. The thrombus was continued from the vicinity of the abscess where the vein was dilated and its wall soft and yellow.

The spleen was soft and pale, not increased in size.

The vermiform appendage, some five inches in length, was directed upwards towards the liver, and intimately adherent to the outer surface of the ascending colon by old adhesions. Its cavity was obliterated throughout the greater portion of its length.

On opening the cæcum an ulcer was found of the size of the palm of the hand. The base was shredily, of a greenish color and offensive odor, composed of the sloughing mucous and muscular coats. At one point, corresponding with the anterior and outer surface of the cæcum, was a pin-hole opening, the peritonæum about which was friable and of a dirty green color. The branches of the portal vein in the vicinity of the cæcum and elsewhere in the mesentery were examined for evidences of thrombosis, but with negative result. The wall of the intestine, except in the immediate vicinity of the gangrenous ulcer, showed nothing abnormal.

It was inferred from the above-mentioned appearances that death was the result of an acute peritonitis from perforation of the cæcum due to a gangrenous typhilitis, and that the latter had also given rise, probably through embolism, to an extensive hepatic pyelephlebitis.

DR. BIGELOW observed in relation to the autopsy that from the symptoms, it was evident that peritonitis existed during the last three or four days of the patient's life.

DR. BOWDITCH asked if the treatment to which the patient was subjected when a child was supposed to have had any influence upon the obliteration of the appendix cæci.

DR. BIGELOW replied that the old obliteration of the cæcum, viewed in connection with the attacks of pain in the abdomen occurring thirty or forty years before, with which it may have been connected, was a striking feature in this case.

DR. FITZ remarked that this case was interesting in showing a tendency to inflammation in certain regions. One severe inflammation healed, the second severe inflammation was fatal.

DR. G. B. SHATTUCK asked if there was any exciting cause for the final attack.

DR. BIGELOW replied that he knew of none. The patient was never in better health than during the past autumn. The family referred, however, to a draught of air in a railway car as a possible exciting cause.

DR. SHATTUCK remarked that if he was correct in supposing the patient to have been a person of peculiarly temperate and regular habits of life, it would seem as if there must have been some organic predisposition to this disease.

DR. LYMAN asked Dr. Fitz if the symptoms in this case were not very slight in comparison with the gravity of the disease.

DR. FITZ replied that the symptoms elucidated by the autopsy were trivial in comparison with what might have been expected from the extent of the lesion of the liver. The disease of the colon might not have caused pain. There were the evidences of a general peritonitis occurring in the last few days: the other pathological processes were of earlier date. Symptoms of disease of the liver are generally confined to this organ or its immediate region.

#### FROZEN SECTIONS THROUGH A THORAX WITH PLEURITIC EFFUSION.

DR. THOMAS DWIGHT showed a series of horizontal frozen sections through the thorax of a child three years old, who had a pleuritic effusion on the right

side. He stated that the body had been frozen lying on its back, and that when the sections were fresh the fluid appeared as ice, which of course subsequently melted. The tissues being hardened while still frozen, the lung had retained the shape into which it had been compressed, and the space occupied by the fluid remained vacant. Owing to the position of the child the fluid was most plentiful at the upper part of the pleural cavity, and but little was to be seen near the diaphragm.

DR. DWIGHT remarked that the œsophagus lay much more to the left than was usual, but he was not prepared to say that this was a result of the effusion.

In the subsequent discussion Dr. Dwight said that he preferred natural cold, and that it was very important that the subject should be thoroughly frozen. The sections while still frozen should be put into cold alcohol.

DR. TARBELL asked Dr. Blodgett if he considered these sections a fair explanation of the position of the pleuritic effusion during the life of the patient.

DR. BLODGETT replied that he knew no reason for supposing that any change in the relations of the fluid and surrounding tissues had occurred since the death of the individual. The fluid was in the chest before death, and the process of freezing had simply solidified everything, so that we now find the effusion in the exact position it occupied in relation to the lung and chest wall while the patient was alive. It seems to prove conclusively that the pleuritic effusion gravitates by its own weight to the most dependent portion of the thorax. It is found most abundantly at the apex in this case, because the body when frozen lay with the shoulders slightly lower than the rest of the trunk, hence the fluid collected at the apex.

DR. LYMAN asked why this was not a perfect demonstration of the normal relations of a pleuritic effusion.

DR. CUTLER said the position of the effusion during life would be exactly the same as after death. The weight of the liquid would lead to its accumulation at the lowest attainable point in the chest cavity. If we change the position of the patient the fluid changes its location so as to constantly seek the lowest part of chest. He had at that time a patient with pleurisy, in whom it was easy to trace the change in position of the effusion when the posture of the patient was changed. The lung floated on the liquid. The heart is displaced to the left, its apex lifted to the level of the nipple. When the patient is lying on the back there is tympanitic percussion in front, when on the left side there is re-onance under the arm, and when sitting the resonance changes to the apex, and there is flatness at the nipple. Dr. Cutler also called attention to another fact demonstrated by the sections of the thorax relating to the height of the apex of the lung in comparison with the height of the shoulder. Percussion at the apex must be gentle, owing to the thickness of the tissues beneath. The heart is more completely covered by the left lung than is generally imagined, and the sternum is underlaid by a large amount of lung tissue. The liver is entirely covered by the lower border of the right lung, and can be percussed only in a limited region in front.

DR. BIGELOW spoke of the surgical relations of the height of the shoulder to the height of the apex of the lung, as being of importance in many of the more serious operations in this region. In persons with high shoulders the apex of the lung is relatively low, and in

those with drooping shoulders the apex of the lung is found relatively much higher. The inclination of the ribs determines the height of the pulmonary apex.

DR. DWIGHT said that in adults the inner border of the clavicle is not a guide to the top of the lung. The only reliable landmark is the edge of the neck of the first rib as it leaves the transverse process of the first dorsal vertebra.

DR. CUTLER thought that tolerably distinct rules are laid down for the location of the pulmonary apex. In hospital patients, however, it is often difficult to obtain satisfactory results on account of the diseased and thickened lung tissue.

DR. BOWDITCH asked Dr. Cutler what he meant by "light percussion."

DR. CUTLER answered, "percussion with the fingers only."

DR. BOWDITCH always presses the finger firmly on the point to be percussed, and then strikes lightly.

DR. BIGELOW spoke of the importance of correct percussion as an element in many surgical examinations, especially that of hernia. In this we need a sharp, dry blow, and not a prolonged, heavy blow. Dr. Bigelow illustrated different kinds of percussion upon the wooden table, obtaining very different resonance according as the blow was short and dry or dull and heavy.

DR. DWIGHT explained the method of making sections. The saw must be very sharp, and the freezing so perfect that the flesh and bones are not distinguishable in sawing. Only the structure of tooth should seem harder than the other tissues. The sections are then washed in warm water to remove sawdust, and placed, still frozen, in cold alcohol, where they must remain till fully hardened, when they will not undergo any change in relations.

DR. BIGELOW stated that when seeking to determine the exact relations of the bladder *in situ*, some years ago, he had found the ice-chest of an undertaker a very satisfactory means of freezing a body in a few hours, so that useful sections could be obtained for photography.

#### SPECIMENS.

DR. CUTLER exhibited the lungs from a case of catarrhal pneumonia, in which were found bronchial dilatation, broncho-pneumonia, and peri-bronchitis. There was a scrofulous condition of the bronchial glands, but no tubercle. He also exhibited the heart of a patient who had expired suddenly the day before. The organ was much enlarged, weighing twenty-four and one half ounces. The left coronary artery was plugged by an embolus at the angle of bifurcation.

Adjourned at 10 30 p. m.

#### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. RITCH, M. D., SECRETARY.

#### DEBATE ON THE TREATMENT OF TYPHOID FEVER.

DR. A. L. MASON opened the debate with the following remarks:—

Having been requested by the President of the Society to say a few words by way of opening a more general discussion of the management of typhoid fever, I will briefly call your attention to the different classes

of cases, as ordinarily met with, and to their varying therapeutic requirements. The-e latter, in a general way, are: (1.) Ventilation and sunlight. (2.) The management of the diet and bowels. (3.) The use of stimulants and other remedies. (4.) The regulation of the temperature. (5.) The disinfection of the stools.

It appears from hospital record books that about seventy-five per cent. of the cases do well if proper attention is given to the points mentioned under the first two headings, with such mild measures as may be necessary for securing sleep and allaying discomfort; that is, under an expectant plan of treatment.

A diet consisting mainly of milk, with plenty of cold water to drink, probably meets the requirements better than any other, and as a rule two quarts of milk will supply sufficient nutriment. Patients will sometimes manage three and four quarts, but it is often found undigested and sour in the stools.

In cases which are prolonged to five or six weeks, without relapse, with slightly raised temperature and quick pulse, from muscular debility, too long continuance of liquid diet is apt to delay recovery. On the other hand, too early ingestion of solids, before the intestinal ulcers are well advanced toward healing, may cause almost immediate aggravation of the symptoms. Examination of the abdomen sometimes enables us to determine whether the unhealed lesions or whether muscular degeneration, with nervous exhaustion, are responsible for the tardy convalescence.

With regard to the bowels, it has been an open question whether any interference is desirable beyond checking too free a diarrhoea. Cases which are costive throughout often do perfectly well, and the absence of peristaltic action during the second and third weeks would be expected to contribute to the healing of the ulcers. But in ordinary cases, with a tendency to constipation, it is better to empty the rectum occasionally by enemata. Few practitioners care to meddle with the bowels any further than that, although the use of occasional laxatives throughout the disease has been said to be of service in relieving the abdominal discomfort and tympanites.

An exception may be made in favor of the German mode of giving ten grains of calomel at the outset, a practice which has appeared to me to give the patient a fairer start, so to speak, than allowing the bowels to remain overloaded. There is probably no greater virtue in calomel than in a dose of castor oil or other cathartics, except that it is easy to administer.

*The use of stimulants and other remedies.* As was before remarked, about seventy-five per cent. of the cases are mild and get well under purely expectant treatment, perhaps requiring a little alcohol towards the close to hasten convalescence. But of the remaining twenty-five per cent. of cases about ten per cent. assume a severer type, and, after suffering from the graver symptoms caused by the higher range of temperature, the deeper intestinal lesions, and the ataxic state, perhaps after having survived hamorrhages from the bowels, bed sores, and an extreme degree of muscular degeneration, these cases also, to some extent by virtue of the rational therapeutics of to-day, rally from the last stages of physical exhaustion and recover.

And, lastly, we have the fatal cases to deal with, varying in number from five to twenty-five per cent., according to the severity of the epidemic, and, if we can draw any conclusions from statistics, according also to the therapeutic measures which are adopted.

Among the requisites for successfully tiding over many critical cases alcohol stands first, a reserve force, however, which should not be wasted by too early use. During the last autumn at the City Hospital, Dr. Stedman adopted the plan, which I continued, of withholding stimulants from all cases in which the pulse did not rise to 120, that is, in the majority of cases, unless there was some special indication for their use, — such as a weak first-sound of the heart, an irregular or dicrotic pulse. These cases did well, and, in fact, the death-rate this year was low, about eight or nine per cent. The epidemic, although extensive, was not severe.

Other drugs which have been found useful are, ergot in ataxic cases, with capillary stasis from a tendency to vaso-motor paralysis; the mineral acids; anodynes; tonics; salicylic acid and quinine, the last two chiefly for their antipyretic influence.

Carbolic acid and tincture of iodine, in doses of a minim each, repeated every two or three hours, have been said to produce remarkable effects from their antizymotic properties. This suggestion, also applicable to the treatment of diphtheria and all of the so-called "germ diseases," has met with some favor in Germany and England.

Before entering upon the fourth consideration, *the regulation of the temperature*, I will read a few extracts with regard to the prevailing death-rates at different places, and the decreased mortality wherever systematic antipyretic treatment has been followed in typhoid fever.

Referring to previous reports in the JOURNAL,<sup>1</sup> I find that Dr. Ernest Besnier's valuable statistics of the prevailing diseases in Paris, for ten years previous to 1877, give a death-rate of 21.31 per cent. in 16,000 cases of typhoid fever.

In the London fever hospitals in 1877 the average mortality was twenty per cent.

At Basle, under expectant methods, there were twenty-seven per cent. of deaths, and about the same ratio prevailed elsewhere in Europe.

In this country no statistics on a large scale have been prepared in any of the cities, but it is doubtful whether a sufficient number of cases from which to generalize would show a lower rate of mortality than fifteen per cent.

In England the number of deaths from typhoid fever annually is more than 8000, and this disease is always an important factor in raising our death-rate, especially to be deplored as the victims have rarely reached the prime of life.

Therefore it is a serious question whether this high rate of mortality cannot be reduced materially in this country, as it has been in other countries.

It is now twenty years or more since Dr. Brand published his first monograph on the systematic treatment of typhoid fever by cold baths, acting on the supposition that the prolonged high temperature was the source of all degenerative changes; attacking the disease through its principal symptom. The zeal of this enthusiastic physician and his remarkable results were not sufficient, however, to popularize such a troublesome mode of treatment, and in his second work, published in 1868, he recognizes the fact that if his methods had not been adopted by Professor Bartels, of Kiel, they would have come to an early end. Later, Jürgensen, Liebermeister, Traube, and other German

physicians of large opportunities took the matter up; after the war the same system was introduced successfully into the Lyons hospitals by medical officers who were forced to admit its merits after observing the practice of Dr. Brand on the French prisoners of war at Stettin; judging from the Croonian lectures of Dr. Cayley delivered in 1880, it has slowly gained ground in London; but in this vicinity, with the exception of a small proportion of the cases at the Boston City Hospital under the care of Drs. Edes, Stedman, Doe, and Draper, it does not appear to have been tried.

Of course in a long disease, with constant calls upon the endurance of the attendants, useless labor is to be condemned, and proper conservatism inculcated.

Professor Gairdner, of Glasgow, where the mortality in the fever hospitals appears to be unusually low under the expectant plan, had a prolonged controversy with Professor Liebermeister on this subject, which was reported in a former number of the JOURNAL.

In Professor Bamberger's wards in Vienna, in 1872, the results of antipyretic treatment were not striking, but in Berlin in the same winter Professor Traube thought that the mortality would be reduced to three per cent.

And, finally, Dr. Brand's last publication announces a death-rate of but 7.4 per cent. in a collection of 8000 cases treated according to his methods in different parts of Europe.

Statistics are to a certain extent unreliable, but I think to only a moderate degree in this case, and as long as we have for some time been in the habit of accepting everything else that is German, the systematic antipyretic treatment of fevers, with all the attendant trouble and expense, should at length command a trial in hospital practice at least.

It may be said, I think, that the type of fever in Boston is not usually very severe. During the month of October and part of November last, more than thirty cases came under my care at the City Hospital. Although their course was often tedious, with a very large proportion of relapses, two cases only were fatal. Several cases continued more than sixty days, and one case over one hundred days. Venous thrombosis affecting one or both legs was noticed in several instances. The relapses were not attributable to errors of diet, and bathing had not been resorted to except in the form of sprinkling or sponge baths.

In this connection the use of salicylate of soda *after* defervescence, as recommended by Professor Immermann, for the purpose of preventing relapses by disinfecting the system, is interesting.

The proper disposal of the stools is a matter of importance too often neglected.

Dr. Edes said that the lighter cases of typhoid, such as were the most of those which he had seen the change in his hospital service, needed but little treatment beyond ventilation, and some attention to diet. Quinia might be used as an antipyretic around the bed to hasten and make more complete the defervescence, but could hardly be considered essential. The cold sponging either with water or dilute alcohol contributed much to the comfort of the patient, and so far as it had any influence upon the temperature was in the right direction, but it could not be regarded as so efficient as some of the other methods of bathing.

In the severer cases he believed in the usefulness of antipyretic measures, especially the cold or gradually cooled bath. This is not supposed to shorten the dis-

<sup>1</sup> Vol. xxviii., page 407; vol. c., page 459.

ease, unless by diminishing the time of convalescence, but to render its whole course milder, especially if the treatment is begun early in the disease.

He referred to his own experience in three successive years in the City Hospital, though without claiming any special value for his own results excepting as agreeing with those derived from a larger number of cases.

Some of the German statistics which had been already referred to by Dr. Mason seemed to him valuable as showing the results in the change of methods of treatment in the same hospitals.

Even the table compiled by Bordier,<sup>1</sup> who is not a strenuous advocate of this treatment, show a decided advantage on the side of bathing.

The labor involved is one of the important objections to the treatment, but he had not encountered so much opposition from attendants as he expected, and could not help thinking that the trouble of bathing was, in part at least, compensated for by the greater freedom from involuntary discharges, the care of which, in severe cases, constitutes a large and disagreeable part of the labor of the nurse.

Quinine is occasionally useful and very materially diminishes the number of baths necessary to keep down the temperature. Its effect is usually felt for many hours after the dose is given. Digitalis appeared to him inefficient in small doses and dangerous in large.

DR. TARRELL said that the treatment of typhoid under his care in the wards of the Massachusetts General Hospital consisted in milk diet, sponge bathing with tepid water two or three times a day, or oftener if the temperature seemed to demand it, and abstinence from drugs. Beef tea was used as a stimulant in some cases but alcoholic stimulants were used comparatively rarely and usually not at all until the third week or later in the disease. The diarrhoea was restrained from becoming excessive by means of small opiates.

Dr. Tarrell was exceedingly skeptical as to the utility of any of the so-called antipyretic remedies employed for rapidly and violently reducing the temperature, and he was not in the habit of giving large doses of quinine nor of using the cold tub bath. His experience was of course limited, but the results of treatment by these methods thus far published in England and America did not appear to demonstrate their superiority to the milder treatment. He also called attention to the comparative rarity of the propagation of the disease by direct contagion, and mentioned the fact that no nurse or other person had contracted the disease from a typhoid patient in the Massachusetts General Hospital for the past six years. The only means of prevention used were extreme cleanliness and the placing carbolic acid in the bedpans before and after using, which could at best be but a slight disinfection of the excreta which were then emptied into the common sewer.

DR. C. E. STEDMAN said that he had reviewed for the forthcoming volume of the City Hospital Reports, 1032 cases of typhoid fever admitted in the last ten years; in the fifteen years since the opening of the Hospital 1181 cases have been treated. The fatality in the first five years was thirteen per cent.; in the last ten years seventeen per cent. This mortality is about the same as that reported by Murchison in the London Fever Hospital from 1848 to 1870. It has

been accounted for by the poor circumstances and constitutions of the patients, but the experience of the speaker confirmed the statement of Dr. Murchison that the fever was more fatal, in a course of years, in the higher than in the lower classes, and Dr. Stedman considered the high rate due to the fact, not only of so many moribund patients being received, but that the number was so large of patients admitted in the second and later weeks of the disease, not having had sufficient food. In one year the mortality was over twenty per cent., in another eight or nine per cent. In trying to tabulate the results of treatment he had been freshly impressed with the untrustworthiness of such statistics. As well as it could be figured, the highest mortality was found among the patients treated by large doses of alcohol, but these were exactly the worst cases recorded in the books. Again, there were nearly four hundred cases which were set down as having had "no treatment," meaning that rest and milk were the chief or only restorative measures adopted. Of these the very mildest cases, seven per cent. died, being patients moribund on entrance who were incapable of receiving treatment, or such as were doing well till a sudden reverse took place. Eleven per cent. of those who had antipyretic doses of quinine, etc., died, nearly all bad cases, twelve per cent. of patients treated mainly by sponge baths succumbed, mostly mild types of fever. The calomel method recorded seven per cent. of mortality, but there were few cases thus treated. Of eighty patients treated by tub baths twenty per cent. died, almost all bad cases. The naked figures unqualified by statement of the stage of the fever when admitted, or its severity, give little notion of the true standing of the facts. Dr. Stedman had faithfully used the antipyretic remedies, quinine, baths, etc., and found, like others, that such means reduced temperature in a marked degree; but the temperature almost always rose again, and he could not see that the course of the fever was at all shortened. It seemed to him that about six hundred of the cases above reported would have done well under expectant treatment and of the remainder very many were saved by timely and proper medical supervision with the best of nursing. Skill in the handling of fever is attained when the physician knows that the time has come to supplement rest, food, and nursing with the administration of drugs and stimuli. Dr. S. found the pulse was his best guide, and though knowing that patients with typhoid fever sometimes die with a slow pulse, had never himself yet lost a patient whose pulse did not range above 120. When the beats neared that number he began to feel anxious, and to stand ready to employ if need be the boldest stimulation. Records of temperature of 105° F. (in one 107° F.) had not alarmed him if the pulse kept down. Several charts showed continued high temperatures with slight morning remissions, and a pulse of 100 or 108; such cases had done well. It is to be noticed that we saw few patients who had not been freely purged before admission, and he had been led to believe that a mild cathartic was not unwholesome early in the disease. For diarrhoea, when there were more than three or four stools daily, he used Dr. Harley's pill of a grain of opium and a quarter of a grain of sulphate of copper or Dr. Pepper's pill of nitrate of silver and hyoscyanus. When stimulants did not moderate high delirium, chloral and bromide were serviceable, or sometimes the wet pack. For himself, were he limited

<sup>1</sup> Journal de Thérapeutique, vol. 3.

to one remedy and one drug, he would cheerfully rely on cold sponging and brandy.

Dr. MINOT had never employed cold baths in the treatment of typhoid fever, but he had tried the effect of sprinkling the patient with ice-water, aiding evaporation by fanning. In this way the temperature can be reduced several degrees in a short time, and the method is easy of application. He had, however, not found any great benefit from it in very grave cases. In two instances in which a high temperature was repeatedly lowered by the effusion, the patients died, but their condition was almost hopeless previously. The temperature can be reduced with much certainty by means of large doses of quinine, ten grains being given every fifteen minutes until the desired effect was obtained. Usually two or three doses are enough. He was accustomed to order stimulants freely in all cases with prostration, and he thought many patients were saved by them. He suggested a trial of the subcutaneous injection of sulphuric ether, as employed by Dr. L. E. Dupuy, of Paris.

Dr. LYMAN said that the practical points in treatment of typhoid had been so much discussed by others that he would allude to only one or two.

In the first place it was not a disease to be cured or cut short; a large proportion needed only nursing and watching, the physician to bear constantly in mind the old maxim of Cullen, "Obviate the tendency to death." It should be remembered always that it is the *heat* which kills, either directly or indirectly. True muscular degeneration, not simply muscular atrophy, it is which weakens the heart, and in a case which runs its normal course without complications it is this weakened heart which is, perhaps, more to be feared than anything else, a fact pointed out by Stokes as long ago as 1839. The difference between bodily heat and fever (quickened heart action as shown by the pulse, and the temperature of the blood as shown by the thermometer) should never be lost sight of. The necrobiotic action of heat upon the tissues, and the simple wasting from deficient nutrition are totally different things, the recognition of which is necessary in our attempts at treatment.

He would say nothing as to cold bathing, having no experience of it, as he had always felt that he could accomplish with cold sponging, cooling drinks, quinine, and alcohol the diminution of dangerous heat without the liability to chill or local congestions.

He was in the habit of beginning with stimulants early, and was governed as to their continuance by the effect upon the pulse, skin, and tongue. He thought it easier to forestall weakness of the heart than to remedy it when once established. As to quinine, he considered it our best and most reliable antiphlogistic, as an antipyretic its effect is more indirect, that is, by its property of lowering heat the tissue changes which cause fever are anticipated. This is the theory of excellent observers, and he was inclined to follow it. He wished also to remark upon the importance, in a prognostic point of view, of uniformity of both the pulse and the temperature, and especially the former, a steady pulse, for instance, of 120 being more favorable than a much lower but more irregular pulse.

Complications, of course, must be treated as such when they arise. Cerebral excitement, of course, counter-indicates quinine; a hard, full pulse, which, though not common, is sometimes found, would lead to caution in use of stimulants; exhausting diarrhoea

would induce extra caution in the diet, and require either an alkali or gentle anodyne; much tympany, the use of turpentine, etc. Every case requires treatment, but in the majority of cases in his experience that treatment would be patience, diet, good nursing, while the few would, from complications or otherwise, require from beginning to end all the therapeutic skill of the most accomplished practitioner.

Dr. MASON said, in reply to a remark of Dr. Tarbell regarding the infrequency with which hospital attendants contract typhoid, that he remembered two cases in nurses in one year at the Massachusetts General Hospital, and several cases at the City Hospital. The poison which conveys the disease either is transmitted through the excreta or it is *not*. If it is, then disinfection of the stools is important, and for this purpose a strong solution of carbolic acid (one to twenty), or, better, a caustic solution of one of the mineral acids, is required. The practical difficulty of carrying out such measures, and of disinfecting other emanations from the body, was recognized, and Dr. Mason stated that he had seen two cases in which he was satisfied that the disease had been conveyed from one person to another by other means than the stools, perhaps by the breath.<sup>1</sup>

Dr. REYNOLDS remarked that the point of the propagation of typhoid fever through the fecal discharges of patients is too important to be evaded or shuffled out of the way. It is conceivable that typhoid fever may have other ways of spreading itself. There is absolutely no question that the disease communicates itself by means of the dejections. The facts which incontestably prove this have become classic in the literature of the subject. These facts are so well known that it is almost an impertinence to rehearse them. Two very striking instances are familiar to every reader of Liebermeister's essay.

"A woman attacked in Ulm returned to her native village, in which no case of typhoid had existed for many years. The excrements of this person were thrown upon a dunghill. Several weeks later five workmen were employed to remove this dunghill. Four of these five were attacked with typhoid, the fifth with gastric fever and swelling of the spleen. The excrements of these patients were buried deep in the dunghill. Nine months afterward the dunghill was wholly taken away by two men. One of these had typhoid, and died of it.

"In Lausen there had not been a case of typhoid for fifty-eight years. An epidemic of one hundred and thirty cases occurred, seventeen per cent. of the whole population. Only those who drank of the running streams were victims. Those who used the wells escaped. In the month preceding this outbreak four cases of typhoid had developed in an outlying house, at some distance from Lausen. The excrements were thrown into a stream near the cottage. This stream communicated subterraneously with the streams that supplied Lausen."

The negative fact that nurses and others in close attendance upon fever patients do not contract the disease, provided due care is exercised in the disinfection of stools, in their instantaneous removal under

<sup>1</sup> On subsequent inquiry of Dr. Rowe, superintendent of the City Hospital, it was found that in two and three fourths years there had been four cases of typhoid among the attendants, three nurses and one ward tender, who had been on duty in the fever wards, where at one time last autumn there were sixty-nine patients with typhoid fever. He considered a solution of the substance sold under the name of "phenyle" a cheap and powerful disinfectant.

proper precautions, and in burying them under dry earth, where that is practicable, is of much weight as to the matter under discussion.

Certain features of the disease, and some points in regard to its management and its treatment by remedies have been much impressed upon me in an epidemic of forty or fifty cases, which occurred in the neighborhood of Boston during the past summer. A large proportion of these cases were under my personal care.

I am anxious to urge in regard to arresting the spread of typhoid that the mild and imperfectly characterized cases are those most likely to do mischief. A servant, "neither sick nor well," whom the household are hardly willing to consider ill, school-children suffering from the abortive form of the disease, these, and other like patients' deposit in the common privy excrements containing the poison, and later, if from any cause members of the family are in a susceptible condition, more than one life may be put in peril from attacks, of which the real cause escapes recognition.

Twelve or fifteen years ago the writer of an exhaustive article on typhoid, in the *British and Foreign Medico-Chirurgical Journal*, laid stress upon a surmise that there exist in typhoid fever two stages, one an initial period, without general septic poison, and a following condition mainly characterized by symptoms which he believed to be due to septic absorption. He declares that this latter class of symptoms rarely appear if at the commencement of the disease care be taken to secure sufficient unloading of the bowels, and if subsequently, by the continuance of mild laxatives and enemata, moderate daily dejections are obtained. I am inclined to admit at least a germ of truth in this statement.

The epidemic to which I have referred was essentially mild in type. It was treated under unusually favorable conditions as to season of the year, good local climate, and opportunity for careful nursing. Severe symptoms of various kinds were, however, in some cases present, giving ground for grave anxiety as to the issue. It seemed to me remarkable that in no one instance of those which I was permitted to watch was there intestinal hæmorrhage, diarrhœa, tympanites, or marked abdominal distress, and I could not help asking myself, whether pursuance of treatment like that just described might not have been in some degree responsible for this favorable result.

Not until we fairly admit the self-limited character of typhoid, the fact that the disease, once present, as inevitably runs its prescribed course as measles or scarlet fever do theirs, can we hope to understand it satisfactorily or to manage it wisely.

Those are golden words in Sir William Jenner's late lecture on the Treatment of Typhoid, in which he describes the aggravation of symptoms which constantly follows the every-day futile attempt to fight off a threatened attack, sometimes by feeding and stimulants, sometimes by violent muscular exercise, and again by drugs, or pictures the mischief which often results from an imagined necessity of returning to a distant home to be ill.

#### HUMAN ACTINOMYCOSIS.

Dr. FITZ presented a brief description of actinomycosis in man and cattle, derived chiefly from the recently published monograph on this subject by Ponlik, of Breslau.

In answer to questions by Drs. Putnam, Porter, and Warren, Dr. FITZ said that he was not aware of any cases which had occurred in this country, but that they may have been overlooked; he also said that the disease worked down under the angle of the jaw as a growth would do rather than by gravitation, and that where the disease was far advanced or was not interfered with early in its course it had proved fatal.

#### BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

WALTER CHANNING, M. D., SECRETARY.

THE Society held its annual meeting on the evening of January 5, 1882.

#### CHANGE OF BY-LAWS.

After considerable discussion, Article IV. of the By-Laws, which specifies that meetings shall be held monthly from October to June, was amended, so that in future there will be but three meetings a year. This change was made in order that the Society might have the better opportunity of advancing the work of the proposed Psychological Section of the Suffolk District Medical Society. Otherwise the Constitution remains unchanged and the Society will continue as before.

#### GENERAL PARALYSIS OF THE INSANE.

The paper of the evening was by Dr. ELISHA S. BOLLAND, first assistant physician of the Boston Lunatic Asylum, and was entitled *A Partial Review of Eighteen Cases of General Paralysis of the Insane*.<sup>1</sup>

In the discussion which followed, Dr. AYER said that the reader had found but few cases which were due to the abuse of alcohol, or venereal excess. His own experience had been the same, when he had had occasion a few years ago to look up a number of cases.

Dr. DENNY inquired whether the diffuse chronic inflammatory processes, such as had been described, together with atrophy and loss of substance, were not also so far circumscribed as to have been most apparent in the cortical tissue of the frontal lobes, the gyri centrales and fossæ sylvii. On receiving an affirmative answer he farther said that diffuse periencephalitic processes, limited chiefly to these parts, had been observed and noted by Schüle, Meynert, Gudden, Emminghaus, and others in general paralysis, and such had been the teaching of his own observations.

Dr. Schüle<sup>2</sup> regards this loss of substance and atrophy, with processes of sclerosis and degeneration in the spinal cord, as almost constant in this disease, and says that such changes are due to chronic inflammatory processes that chiefly affect the frontal lobes, the gyri centrales, and the convolutions about the fossa sylvii.

Professor Meynert considers general paralysis to be a diffuse degenerative process leading to atrophy, affecting by preference the cortical portions of the frontal and parietal lobes, with their meninges — a diffuse chronic periencephalitis, or a chronic interstitial inflammation.

Lays<sup>3</sup> defines the pathological process as an inter-

<sup>1</sup> Vide page 172 of this JOURNAL.

<sup>2</sup> Section-entzündung bei Geisteskranken, 1874, page 158.

<sup>3</sup> Traité Clinique et pratique des Maladies Mentales, 1881, page 627. Gaz. des Hôpitaux, No. 47, April 20, 1878.

stitial sclerous hyperplasia leading to the obliteration of nerve-tubes and cells, analogous, in many ways, to the lesions of *tabes dorsalis*. "This same hyperplasia of neuroglia produces the phenomena of *tabes dorsalis*, paralysis agitans, and disseminated sclerosis, differing only in their symptoms according to the localization of the morbid processes."

Voisin<sup>1</sup> is also of the opinion that the proliferation of neuroglia compresses and finally atrophies the active elements of the brain.

Mendel<sup>2</sup> states that Meynert's plasma-cells, or Deiter's cells, are multiplied in general paralysis, that is to say, as above that there is a proliferation of neuroglia in this disease.

Emminghaus<sup>3</sup> describes the pathology of a case of general paralysis as one of diffuse cortical disease of the frontal lobes and central convolutions.

Dr. Von Krafft-Ebing<sup>4</sup> refers the pathology to a vaso-motor paresis, induced by excesses, over-train, etc., which, through the vascular distribution of the carotid, locates chiefly in the frontal lobes; lymph stasis follows in the pia and brain substances with infiltrations of colloid and albuminous substances, etc., into the perivascular lymph spaces. Thus tissue changes occur leading to a proliferation of the connective tissue of the pia, vessels, and neuroglia, terminating in sclerosis and atrophy of nerve elements.

Professor Meynert,<sup>5</sup> in weighing the different portions of the brain to determine the relative proportion of atrophy or tissue change leading to loss of substance, states in an article on the subject of the weight of the individual portions of the brain, as quoted by Mendel, that the loss of weight in general paralysis is mostly confined to the hemisphere, affecting, as before stated, the frontal and parietal lobes by preference.

Professor Gudden, of Munich, thus divides the brain in weighing the separate parts, and his conclusions tend to corroborate the localization of atrophic processes in the anterior lobes, more especially in general paralysis.

Having separately detached the two lobes of the cerebellum, the cerebral ganglia are dissected out of the hemispheres, with the pons Varolii and medulla oblongata. Then, the hemispheres having been separated through the corpus callosum, the frontal lobes are divided from the rest of the brain by incisions through the sulcus centralis Rolando and each of these seven portions resulting are weighed and compared.

The details reported by the reader in regard to reflex phenomena are interesting and but comparatively few observations are published bearing on this subject in connection with general paralysis.

Dr. Jakob Weiss,<sup>6</sup> while clinical assistant to Professor Leidesdorf, published fifteen cases of myelitis paralytica, as he terms general paralysis, in which he uniformly found granular lymphoid bodies, etc., indicating a myelitic form of affection in the cord.

In all these cases the posterior lateral columns were the seat of disease, which he does not regard as a secondary descending process, but agrees with Westphal that the brain and the cord in general paralysis have

a similar predisposition toward this disease, that this simultaneously affects both with varying intensity.

The tendon-reflex phenomena were increased in five of the number, and choroid movements appeared in two, while in the remaining cases nothing in regard to this point is mentioned.

Dr. Claus,<sup>7</sup> in his admirable analysis of clinical and post-mortem evidence in nineteen cases of general paralysis, found in three cases where the degeneration affected the posterior columns as far down as into the lumbar cord that there was an absence of tendon-reflex phenomena.

In the succeeding four cases in which the posterior columns were involved to less degree as far as the first lumbar vertebrae there was a moderate knee phenomenon, and at times a foot phenomenon could be induced.

A third group of four cases comprised those in which there was simultaneous degeneration in the posterior and in the postero-lateral columns, and in which the knee phenomenon was quite marked, and at times the foot phenomenon also.

Finally a fourth group of four cases included the degeneration of the posterior lateral columns alone, wherein the knee phenomenon was always very strongly manifested, and in which the foot phenomenon was always intense, appearing sometimes in the form of clonus.

Thus the reflex phenomena vary with the location and intensity of the morbid process and in accordance, apparently, with the facts of anatomy.

Cases of progressive locomotor ataxia are occasionally met with in which it is very difficult to diagnose correctly between this form of disease and general paralysis, and cases are reported tending to show that progressive locomotor ataxia may terminate in general paralysis.

Such an instance came under my observation some ten years ago. A gentleman about fifty-five years of age returned from Europe, bringing with him a written diagnosis of progressive locomotor ataxia from Dr. Duchenne. The symptoms when, some time later, he was brought to an asylum were those of general paralysis, with which he died.

Dr. Fisher remarked that Dr. Boland had prepared a list of questions for use in examining cases of suspected general paralysis occurring at the City Lunatic Asylum. It was of great importance that the clinical record should be complete for comparison with the record of post-mortem appearances. The past year careful autopsies had been made by Dr. W. W. Gannett, pathologist to the hospital, assisted by the staff. Microscopic examinations were, in all cases, made of the brain and cord both in the fresh and prepared state. It was remarkable how much organic change was found, and in what variety in cases of general paralysis.

Dr. Fisher read the diagnoses of Dr. Gannett in four of the cases read by Dr. Boland as follows:—

(1.) General post-mortem staining of tissues. Slight chronic leptomeningitis. Hydrocephalus externus. General atrophy of brain with edema. Chronic ependymitis. Etat criblé of white matter and basal ganglia. Chronic endarteritis of vessels at base of brain. Double hydrothorax. Chronic adhesive pleurisy. General vesicular emphysema. Hypostatic congestion of lungs.

7 Ueber Erkrankungen des Rückenmarkes bei Dementia paralytica und ihr Verhalten zum Kline-Phänomen, etc. Allg. Zeit. für Psych., 2 Heft, 33 Band, 1881.

<sup>1</sup> *Traité de la Paralyse Générale des Aliénés*, page 432, 1879.

<sup>2</sup> *Die progressive Paralyse der Iren*, page 53, 1880.

<sup>3</sup> *Ein Fall von progressiver Paralyse*, von Dr. Emminghaus, *Irenfreund*, No. 12, 1879.

<sup>4</sup> *Lehrbuch des Psychiatrie*, 1879.

<sup>5</sup> *Das Gesamtgewicht und Theilgewicht des Gehirns*. *Vierteljahrs. für Psychiatrie*, 1867, ff. 2.

<sup>6</sup> *Psychiatrische Studien aus der Klinik des Prof. Leidesdorf*, 1877.

Limited atelectasis of lungs. Post-mortem softening of stomach. Fibro-myoma of stomach. Fatty infiltration of liver.

(2.) Decubitus. Edema of pia mater. Atrophy of gray matter of frontal convolutions. Pigmentation of ganglion cells in gray matter of convolutions and of basal ganglia. Recent pleurisy with effusion. Putrid bronchitis. Gangrene of lung. Senile atrophy of spleen and kidneys. Diphtheritic inflammation of the bladder. Suppurative prostatitis with calculi. Chronic endarteritis of coronary arteries.

(3.) Decubitus. Hyperostosis of skull. Chronic external pachymeningitis. Edema of pia. Atrophy of brain. Chronic internal hydrocephalus. Chronic ependymitis. Ossifying leptomeningitis of cord. Chronic circumscribed pericarditis. Brown atrophy of heart. Bronchitis. Intermural fibro-myoma of uterus. Brown atrophy of liver with fatty infiltration.

(4.) Chronic internal hæmorrhagic pachymeningitis. Chronic leptomeningitis. Edema of pia. Atrophy of brain. Chronic endarteritis of basal vessels. Chronic ependymitis. Miliary aneurisms. Chronic circumscribed pericarditis. Chronic adhesive pleurisy. Bronchitis. Chronic emphysema. Chronic interstitial nephritis. Pyelitis. Cystitis. Stricture of urethra. Lime infarctions of kidneys. Chronic endarteritis.

By careful comparison of the symptoms and lesions in a large number of accurately observed cases, some light may be thrown on cerebral localization and the pathology of general paralysis.

## Medical and Surgical Journal.

THURSDAY, FEBRUARY 23, 1882.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

### PUERPERAL FEVER AND INFERIOR ORGANISMS.

In May, 1875, being in London, it was our fortune to be present at one of the sessions of the Obstetrical Society when the memorable debate on puerperal fever was in progress. With interest freshly awakened by what was then heard from the lips of such men as Robert Barnes, the late Mr. Callender, and others, the reports of the subsequent sessions were followed. Much of the best talent in medicine and surgery of the United Kingdom was enlisted in the discussion, but at its close none of the questions formulated by Mr. Spencer Wells in opening the debate, nor those which came up during its progress appeared to have advanced much towards settlement. The *London Lancet* concluded that our facts were probably defective, that it might still be wise to wait for fresh material. It asked: "Will the final, solving, evidence come from the bedside or the laboratory? Hitherto the chemist pure has done little. Will the man who combines chemistry with a profound know-

ledge of histology and the changes wrought in the body by disease, aided by experimental inquiries, do more? There is greater hope in this direction. In the mean time the clinical physician will not be tempted out of his path by the golden promise of bacteria."

During the progress of two severe and protracted cases of puerperal pyæmia the past year, one of which recovered, the doubts and uncertainties involving the general subject were forced upon our attention anew. Since the debate above mentioned the rôle of the living germ in the processes of disease has been steadily assuming large proportions as one of the most fruitful questions of the day in the world of science. Its investigation has opened paths into regions among the most obscure, and the dwellers in darkness have begun to see great a light.

In the midst of such reflections the *Index Medicus* — and it is with pleasure that we pay tribute to its usefulness — suggested to our consideration a book, published in Paris in 1880, whose title rendered into English runs thus: —

"Puerperal Fever and Inferior Organisms; Pathogeny and Therapeutics of Infective Accidents Following Childbirth. By Dr. J. Amédée Doléris."<sup>1</sup>

Let us try to judge by brief examination of the book whether, peradventure, Dr. Doléris is the man whose advent the *Lancet* hoped for.

In 1874, the year just preceding the London debate, Dr. Doléris, as externe at the obstetrical clinique under Dépaül, was following attentively a certain number of puerperal patients, observing all the degrees and all the forms of the malady, and by the aid of rigorous control of the autopsies was recording remarks destined to be put to profit later. In 1879, as interne at the maternité of the Hôpital Cochin, under M. Lucas Championnière, he returned to the task which he had assigned himself. The first part of his labor had been devoted more especially to anatomico-pathological researches. The second portion, "stimulated by the brilliant success of the new treatment, of which M. Championnière is the patient and devoted apostle," took the direction of "seeking the material demonstration of the terms of the problem of which the solution seemed so certain." Faith had then come to him after doubt, and he was no longer incredulous when he sought to determine whether the marvelous effects of the Listerian method had their *raison d'être* in the suppression of the injurious organisms of the atmosphere.

Dr. Doléris relates how thereafter M. Pasteur, with whom he came into relations while practicing an autopsy on a patient of M. Hervieux at the Maternité, persuaded him to undertake the study of the organisms of puerperal fever, and offered him the support of his precious counsel in the long and difficult task.

The clinical and anatomico-pathological considerations of the work are based upon the observations of 1874 at the clinic, and upon those of 1879 at Cochin. The micro-biological study is deduced from the observa-

<sup>1</sup> La Fièvre Puerpérale et les Organismes Inférieurs, Pathogénie et Thérapeutique des Accidents Infectieux des Suites de Couches. Dr. J. Amédée Doléris. Paris: J. B. Baillière et fils, 1880. Pages 334.

tions at Cochín, and from isolated cases at La Charité, Lariboisière, and other hospitals, the study of which was made at the laboratory of M. Pasteur. The narrative of these results constitutes the original side of the work. In two short chapters is condensed an excellent critical review of the history of puerperal fever, and of the actual state of science concerning it.

Puerperal fever, or whatever one pleases to call the disease (the author sees no difficulty in employing the term), is, in the most complete acceptance of the word, an intoxication. This opinion is general, and reckons no adversaries. The most pronounced localizers have long renounced the consideration of the lesion alone in the malady. The lesion is for them only a necessary phenomenon. For them the question is limited to infection through the wound. The condition *sine qua non* of toxæmia is a raw surface analogous to, even identical with, a surgical wound.

"No wound, no infection," is a doctrine which leaves out of sight many incontestable facts, such as the transmission of infection to the foetus, infection before delivery, and contamination of individuals not in the puerperal state.

In France it is an opinion well established to-day that one newly delivered is in the same condition as one wounded, with this unfavorable circumstance, that the wound (uterine wound) is of especial susceptibility, and that it is but little accessible to the use of the customary dressings of a wound. Phlebitis and lymphangitis exist surgically and obstetrically by the same incitements. These facts are fully and repeatedly established. The question which dominates all is, What is the element whence the infection proceeds? A wound unprovided with a septic substance cannot be the origin of an intoxication. It is almost a pathological axiom that certain wounds bring septiciæmia while others remain without effect upon the organism; that there are wounds which become maladies, and others which remain merely wounds.

Puerperal infection borrows from the particular state of the newly delivered only the enfeeblement and diminished resistance to the morbid agents which parturition carries with it. Parturient women are wounded, and peculiarly wounded. Hemorrhage, the nature of the injury, nervous shock, the exhaustion due to labor joined to diminution of blood globules and special conditions connected with modifications of the blood, as well as with those of the tissues themselves, form the first group of predisposing general conditions. The nature of the wound, its deep situation, the existence of matters in process of decomposition or disintegration, decomposing blood-clots, retention of placental débris, the production of external wounds exposed to the contact of exterior germs or of interior liquids already containing such germs, deep contusions of soft tissues compromising their vitality or determining necrobiotic processes, the existence of numerous vascular meat open at the uterine surface, the energetic rôle of the absorbents which begins after confinement—such are the circumstances which constitute the second group of local predisposing causes. The infection is not always identical; our author accords a preponderating

influence to the ætiological difference, to the special variety of the germ. The morbid germ differs according to the different forms of the malady, and, what is more exact, according to the lesions of the malady. Thus pus always contains a determined form of organism; this is the micrococcus in pairs. It may contain other forms.

Passing over the living organisms in the atmosphere of the lying-in rooms, let us glance at the micro-organisms found in the genital organs and the lochia as presented in notes of twenty-one cases. These show that the examination of the lochia of women of almost equally good appearance revealed organisms in some cases and their absence in others. The presumption that those of the first category would fall ill was realized.

The natural protection of the vagina by the normal occlusion of its orifice becomes less secure in proportion to the dangers, that is, the organisms, are multiplied; and as soon as its portal is crossed its situation is exceptionally bad, as affording a *foyer* convenient for the development of germs to which air is fatal; and this without prejudice to certain other common organisms of putrefaction which may live in the air or out of it. The former increase the faster from the presence of the latter only because the latter take possession of the small quantity of oxygen from the tissues and liquids.

These are not advanced by the author as hypotheses, but as facts proven beyond doubt. Many organisms seen by the microscope in the lochia have no harmful action—the common bacteria, for example—although taking an active part in the decomposition of liquids. They flourish in the air and are harmful only as they clear the way for the septic bacteria. The micrococcus in couples, which Pasteur considers the agent of suppuration, is met with almost always. With this organism, as with some others, it is the quantity which determines the peril. Although the quality goes for much, yet one is more easily relieved of very harmful micro-organisms if present in very small numbers than of less injurious ones if they are very abundant.

Chaplets and bacteria sometimes accompany the micrococcus, *en point double*. There is another micro-organism whose resemblance to the micrococcus is great. Their sole difference is in volume. This micro-organism is triple or quadruple the size of the ordinary double point and is more brilliant. Like that it unites by twos, threes, and fours, rarely more. It never forms true chaplets. It has seldom been encountered except among women very ill, and sometimes at the autopsy in the liquid of the lymphatics and peritoneum. On one occasion it was contained in the blood and rapidly multiplied in the liquid of culture. Whatever be the variety, since we must not expect to base upon the form alone an element positively distinctive, it is the quantity especially which causes the danger. An exception is made in favor of a little vibron which often swarms in the first part of the genital canal, and is often found among women who do the best; after the sixth or seventh day.

The second question bearing on danger is the time of the presence of organisms. The second and third days are more serious; the sixth and seventh very much less so.

Third comes the question of their seat. The most dangerous, namely, those to which air is fatal, are to be sought in the deepest part of the genital canal.

(To be continued.)

#### CHANGES IN MEDICAL JOURNALS. THE JOURNAL OF OTOTOLOGY. THE JOURNAL OF NERVOUS AND MENTAL DISEASE.

THE publication of the *American Journal of Otology*, beginning with the first number of the fourth volume, has been transferred to Boston. The *American Journal of Otology* is issued quarterly, and was founded three years ago with the purpose of establishing in this country an independent journal devoted to the advancement of the knowledge of the branch of surgery which it represents, by providing a medium for the publication of original papers on subjects pertaining to physiological acoustics and aural surgery, and of reviews of papers on these subjects published elsewhere.

In addition to its departments of Original Communications and Reviews there is given with each number (quarterly) a Bibliographical Index, including the titles of all the most important books, theses, and papers on aural surgery published in journals or in the transactions of societies which have appeared during the preceding quarter, and also of such publications on the subject of acoustics as may have a special bearing upon practical otology.

A review of the original communications in the three volumes already published shows this *Journal* to have a practical value for the general practitioner, each number containing reports of cases embodying the clinical work of the editorial staff and of other contributors.

With the exception of the *Archives of Otology* the *Journal* is, we believe, the only scientific periodical in the English language devoted to the above subjects, and differs somewhat in its scope and character from the *Archives* in so far as that exchanges translations of articles with the German *Archiv für Ohrenheilkunde*. The editorial direction remains unchanged, Dr. Clarence J. Blake, of Boston, continuing at the head of the staff, which consists of able representatives in the principal cities of the country.

Whilst the *Journal of Otology* has changed its home without changing its editors, the *Journal of Nervous and Mental Disease*, on the other hand, has, we understand, changed its editorial direction somewhat without changing its home. Dr. J. S. Jewell has resigned the editorial management to Dr. W. J. Morton, though joining Drs. Seguin, Hammond, and others as an associate editor.

We wish both of our contemporaries a continuance of prosperity and usefulness under their present conditions.

#### THE VALUE OF STATISTICS AS TO INSANE ASYLUM MANAGEMENT.

IN this number of the *JOURNAL* is printed a letter from Dr. H. P. Wilbur, correcting some records relative to mechanical restraint in the insane asylums of Massachusetts which were published in an article on Chemical Restraint in the Management of the Insane, written by him for the December number of the *Archives of Medicine*. The correction of these errors shows the fair intention of the author, but it is evident to any one familiar with the subject that the whole table is utterly untrustworthy. Its inaccuracies, however, do not affect materially the accuracy of Dr. Wilbur's conclusion that the use of chemical restraint is not greater in Great Britain because of the non-use of mechanical restraint, and they would hardly deserve attention had not the editor of the *Archives* added the following postscript to the article:—

"The author of the above editorial article had intended not to name the various American asylums set down in his table, but had referred to them simply by numbers. I consider the subject one of such great importance to the medical profession, and to the public generally, that I have assumed the responsibility of reinserting those names. This being done, persons interested in the more humane and intelligent care of the insane will know where to look for remnants of barbarous measures, for over-drugging, and for excessive suicide."

This asserts that the table is valuable as a basis for comparison, whereas it is absolutely worthless for that purpose, because the term "occasion" has evidently been used by different superintendents to designate periods of time varying in duration from an hour to a month, and because the definitions of restraint and seclusion vary so much; correct conclusions from a comparison of the records are therefore simply impossible. This is strikingly shown by the fact that two hospitals in the same State, having about an equal number of patients, report respectively 48 and 2547 "occasions" of restraint, and yet the State official who makes the return says: "I am satisfied from a somewhat careful inquiry that, if any, there is no substantial difference in the amount of restraint practiced in our hospitals. The difference is in the manner of reporting." When the manner of reporting may cause a difference of fifty-fold the usefulness of facts for scientific purposes may be fairly questioned. A similar difference in the manner of reporting has evidently existed in other institutions, and it is also true that superintendents differ very decidedly in their opinions as to what constitutes "restraint" and "seclusion." The statistics of lunacy are such a fertile source of erroneous conclusions that it is well for one using them to satisfy himself thoroughly as to their accuracy.

—The *Medical Press and Circular* learns "with delight that an anti-vivisectionist who subscribes twenty pounds yearly towards carrying on the anti-scientific agitation has been fined for maltreating an unoffending animal in his possession."

## MEDICAL NOTES.

— Dr. Samuel Cabot has resigned his position as Surgeon to the Massachusetts General Hospital after an active and distinguished service of thirty years and three months. Dr. Cabot's resignation has been accepted by the Trustees, who at the same time expressed their appreciation of his services by appointing him Consulting Surgeon to the Hospital.

— The following sonnet, written for the occasion by Dr. Oliver Wendell Holmes, was read by Prof. H. P. Bowditch at the annual dinner of the Harvard Club, New York, February 21, 1882:—

Yes, home is sweet! and yet we needs must sigh,  
Restless until our longing souls have found  
Some realm beyond the fireside's narrow bound  
Where slipped ease and sleepy comfort lie,—  
Some fair ideal form that cannot die  
By age dismantled and by change uncrowned,  
Else life creeps circling in the self-same round  
And the low ceiling hides the lofty sky.  
Ah, then to thee our truant hearts return,  
Dear Mother, *Alma, Casta*,—spotless, kind!  
Thy sacred walls a larger home we find,  
And still for thee thy wandering children yearn  
While with undying fires thine altars burn  
Where all our holiest memories rest enshrined.

— Another case has been added to the few recorded in which the spread of typhoid fever has been prevented by a reliable system of water purification. In a report by the Surgeon-General of the tenth (Prussian) Army Corps, dated September 17, 1881, we read that a small epidemic of typhoid occurred twice in the military hospital at Emden (Hanover), first during the winter 1875-76, and again in 1877. The drinking water was contaminated by organic matter, and stated to have been the sole cause of the latter outbreak. In 1878 two of Bischof's spongy iron filters were obtained, and the Surgeon-General of the Corps reports that since their introduction no further epidemic of typhoid has taken place. The water, which previous to the use of the filters was flat and rather repugnant to the taste, has since been bright and palatable. The same results have been obtained in the military stations at Shoeburyness and Fort George. In the former, zymotic diseases, especially typhoid, were prevented, whilst very prevalent in the neighborhood. In the latter, they were arrested, as will be seen by comparing the nineteenth and twentieth Army Medical Reports. The same filters were ordered in 1878 by the Prussian Military Administration, during a severe epidemic of typhoid fever, for Fort Alexander at Coblenz. Since the introduction of the filters not a single further case of typhoid occurred up to the commencement of the present year, when, the well having in the interval been deepened, the filtration through spongy iron was discontinued. It is remarkable that shortly after this another epidemic of typhoid should have broken out.

— Sir Robert Christison, of Edinburgh, died January 27th in his eighty-fifth year. He studied toxicology with Orfila in Paris. On his return to Edinburgh

he was appointed professor of medical jurisprudence at the university in 1822, holding this chair for ten years, when he was made professor of materia medica, which position he held for forty-four years, till 1877. He presided over the meeting of the British Medical Association in Edinburgh in 1875. He was a member of the General Medical Council from 1858, the year of its establishment, until 1873. He was physician in ordinary to the queen in Scotland, and the author of the standard English work on poisons. At the time of his death he was vice-president of the British Medical Association.

— Deaths under chloroform are again recurring with distressing frequency in England, according to the *British Medical Journal*. An inquest was held at Malvern Wells on Saturday, on the body of Charles Nelmes, aged fifty-one, who died while under chloroform. It appeared that deceased had sustained a dislocation of the shoulder, and he waited upon Mr. Haynes, surgeon, who attempted to reduce it by ordinary means, but failed to do so. Mr. Haynes then decided to administer chloroform, but before doing so he examined deceased's heart, but could detect nothing which should prevent him from administering chloroform. He accordingly gave the deceased small doses. Soon afterwards deceased's legs became convulsed, and he held them, but death took place in a very short time. Dr. Pike and others said they should have acted precisely as Mr. Haynes had done. In cities and towns it was easy to get a medical man to assist in administering chloroform, but it was different in the country. The quantity administered was not excessive. Mr. Brown, surgeon, who made a post-mortem examination, said that deceased was in such a state of health that he might have died at any moment. The jury returned a verdict of "Died from natural causes, accelerated by chloroform judiciously and properly administered," but some of the jury deprecated the practice of the profession in putting persons under the influence of chloroform "single-handed." A case is also reported in the daily papers of Mr. T. Fenton, of Broughtly Ferry, near Dundee, who was about to undergo an operation for sympathetic ophthalmia. "Two medical gentlemen attended from Dundee, and Mr. Fenton was put under the influence of chloroform, but it had not been administered many minutes before he died." We should be glad to have medical details. We hear also of a third case of death under chloroform, said to have occurred at the Royal Free Hospital this week, of which, however, we have not yet received details or seen any published report.

— Drs. H. C. Wood and Formad desire to know of the existence of an epidemic of malignant diphtheria, in order that they may continue their research upon the nature of the diphtheritic poison. Dr. Formad will go to any locality within eight hundred miles of Philadelphia. Letters may be directed to the University of Pennsylvania.

— The *Japan Daily Mail*, of Yokohama, says: "Dr. Tanner will have 'to take a back seat,' as his countrymen would put it. His fast of forty days has

been completely put in the shade at Pahlhanpore, British India, where a religious mendicant of the Jain caste is reported to have just completed a ninety-one days' fast successfully. An eye-witness describes in a Surat paper the appearance of the man on the last day of the penance. The 'saint,' says the writer, "underwent a fast of eighty-six days last year, and has been more or less accustomed to this form of infliction. When seen on the ninety-first day of the recent fast, his abdomen had so much subsided as to form the shape of a pit; the veins were much swollen, and he seemed to speak only with great effort. He was seated on a blanket in a corner, and had near him the sour water of curdled milk, which he sometimes drank. He seemed, however, to be capable of physical exertion, and up to the last day procured the curdled milk-water for himself. He was all along engrossed in prayer, and held no communication with other men except on religious topics. The man has spent his life in strict asceticism, and has denied himself all food and luxury save what might be got from milk-water, bread, and yellow rice. His bedding consists of an ordinary blanket and nothing more. Many Jains undergo penances, in the shape of fasts and other self-infliction, but it is said that this man's efforts in this direction are unapproached by even his most devoted co-religionists, and he has drawn to himself a large following. He accepts, however, no presents and no fees.

### Disseclanp.

#### RESTRAINT IN MASSACHUSETTS INSANE ASYLUMS. A CORRECTION.

MR. EDITOR, — In an article on Chemical Restraint, in the December number of the *Archives of Medicine*, a mistake occurred in the statistics given of the insane asylums of Massachusetts, which I desire to correct in a Massachusetts medical journal.

To meet a statement often made in the United States that in the British asylums for the insane the necessity for restraint by mechanical appliances is obviated by the free use of stupefying drugs, I prepared some comparative tables, showing the relative use of mechanical restraint and the administration of soporifics and sedatives in the asylums of the two countries.

I here present in a corrected form the statistics of Massachusetts asylums for a month: —

| Name of Asylum. | No of patients Monthly occasions of restraint. | No. restrained. | Monthly occasions of seclusion. | No. secluded. | Average number to whom chloral was administered daily. | Average number to whom hyoscyamine or other narcotic was administered to any extent. |
|-----------------|--|-----------------|---------------------------------|---------------|--|--|
| Worcester . . . | 551  | 69              | 71                              | 22            | No record.   |  |
| Danvers . . .   | 643  | 138             | 161                             | 5             | 3  |  |
| Northampton . . | 371  | 232             | 218                             | 26            | None.  | None.  |
| Taunton . . .   | 574  | 29              | 7                               | 29            | None.  |  |

The report of the Taunton Asylum was somewhat indefinite; it read thus: —

"Under restraint, from September 1st to October 1st, of men 2.1 per cent.; of women, 5.1 per cent. In seclusion, during the same period, of men, 1.05 per cent.; of women, 1.4 per cent.;" which I have interpreted, in the table, as referring to the number of individuals restrained or secluded, and not to the occasions or duration of the periods of restraint or seclusion.

Yours truly, H. B. WILBUR, M. D.

#### INOCULATION OF TYPHOID. PROPHYLAXIS OF TUBERCULOUS DISEASES.<sup>1</sup>

MR. EDITOR, — In continuation of my remarks in a previous issue of the *JOURNAL*, I beg to state that, in my opinion, intestinal typhoid inoculation becomes of still greater value when considered in relation to the power it possesses of arresting and abolishing phthisis, the mortality from which is, in the long run, about three times greater than that of any other known affection.

So entirely do the processes of typhoid disease wear out and cast off exuvie on which tubercular phthisis might otherwise feed, that of all those in the circle of my acquaintance or of whom I have exact knowledge, who, having had typhoid fever, entirely recovered therefrom to the standard of good health, I do not know a single instance in which any one of them has thereafter become a victim to phthisis, except where the last dregs of an hereditary or acquired tuberculous diathesis were made to crop out, owing to some morbid condition of lung compressing its tissues, provoked, possibly, by hospital atmosphere, or bad food, and assisted, perhaps, by a concurrent attack of variola, rubella, or pulmonary abscesses from pyæmia or purulent infection. Without these antecedents, with very rare exceptions, they all enjoyed complete immunity from phthisis. The most solid form of pulmonary engorgement symptomatic of, caused by, and engrafted on, rheumatic fibro-bronchitis, is also a most inviting nest, where the mere remnant of a tuberculous diathesis is most likely to deposit cheesy matter in and throughout its condensed substance. Entertaining these views, one cannot help regarding typhoid disease as having much to do with the prophylaxis of tuberculous disease. It is curious to note, also, how incipient phthisis is arrested, and its plot-work broken up and dissipated, by the supervention of typhoid disease. It must be seen, therefore, that to people who have had typhoid fever, and have perfectly recovered from it, may be accorded what quarantine officers call a clean bill of health, so far as any liability to phthisis is concerned. Or, to explain more perfectly, and make the subject better understood, it may be said that typhoid fever and tubercular phthisis appear as though standing towards each other in the light of acute and chronic affections of the same order, and that the process of typhoid disease consumes and exhausts the inherited or acquired *matrices morbi*, which would otherwise go to the development and sustenance of tuberculosis. Therefore, however important typhine intestinal inoculation may be to prevent continued fever in after life, it is for individuals inheriting a tuberculous diathesis of far greater value as a guard against pulmonary consumption.

But for want of space many examples might be

<sup>1</sup> Continued from page 119.

given to show that typhoid fever is a true guard against phthisis, and the following cases are intended to show, to a certain extent, that typhoid disease is both a guard against and a remedy for incipient tuberculosis, whether in the lungs or elsewhere.

A young lady, aged seventeen, who had lost her mother from consumption, was pronounced by competent authorities to be suffering from the inherited malady, marked by cough, hectic, and loss of flesh and strength. At this juncture she was so fortunate as to contract typhoid fever, prevailing in the neighborhood at the time. She was ill for six weeks, and had a tedious convalescence, but after getting well found she had recovered from her lung trouble. Examining her some years subsequently, I could discover nothing but slightly prolonged expiration at the top of the left lung, more marked on the dorsal surface than in front.

Mr. H. W., now in the enjoyment of perfect health, and active at eighty-eight, lost five brothers and a sister from consumption. His immunity from that disease was no doubt due to his having had as a youth an attack of fever lasting six weeks, and pronounced by Drs. Brown and White, both Dublin University men, practicing medicine at that day in Baltimore, to be typhoid.

Forty-two years ago, S. B., a clerk, born of consumptive parents, and aged nineteen, had two nests of tubercle at the top of the left lung, one deposit being in the subclavicular region, while the other was beneath the superior dorsal surface, just above the spine of the scapula; over the latter was heard the click, death-knell of Baron Louis, characteristic of softening, and in front the crepitant r  le of milary tubercles. He had had one slight hemorrhage. There had been for a period night sweats, hectic, and some emaciation, all of which still continued. While in this condition he, fortunately, contracted typhoid fever, prevailing at the time in the locality. He was ill for thirty days, after which his convalescence, although steadily and uninterrupted, was protracted for months, for while recovering from the fever he also convalesced from the lung trouble, restoration from which latter, the course of his life and occupation remaining the same, could only be attributed to the changes wrought by typhoid disease. He afterwards enjoyed good health for about twenty-three years, at the end of which inexact period he died of rheumatism seated in the white fibrous tissues of the primary bronchi of the right lung, followed by intercurrent or symptomatic pneumonia, and rheumatic pericarditis. A post mortem showed at the points in the left lung, before described, a little tucking in of the pleura, beneath which was some catenaceous deposit surrounded by melanotic matter, relics which recovery from phthisis could alone have left there.

Where the lung trouble is grave typhoid fever may arrest for a time the progress of phthisis, but cannot, by restoring serious structural alterations, give lasting relief. In other words, it cannot cure what is incurable. It would not cure a lung having a large anfractuous cavity lined with a pyogenic membrane, nor one studded with a large amount of crude, tuberculous deposit, as in the following case.

A youth, student of medicine, in whose family there had been, on both sides, cases of phthisis, was found to have extensive crude tuberculous deposit in the upper and middle lobes of the right lung. At this juncture he contracted typhoid fever, which, marked by rose-

colored spots and sudamina, ran the usual course, during which time no softening or other apparent change in the tuberculous deposit took place. After his convalescence from the fever had been completed, and he had picked up his usual flesh, I was asked to see him at his father's country place in Maryland, and found that the cause of alarm was a profuse pulmonary hemorrhage, amounting to more than a quart. To keep the crude tubercles from maturing, ripening, and softening, the weather being very warm, I sent him off to Minnesota, where, during the following winter, he drove with the bishop of that State, when visiting his diocese, eighteen hundred miles, and the winter next succeeding he drove with this distinguished divine and great friend of the red men fourteen hundred miles. The following summer, during a very hot period the last of June, he returned to spend two weeks in Baltimore. It being nearly two years since he last came under my observation, I found the same crude tubercularization, and that no change had taken place except the occurrence of emphysema throughout the left lung, and considerable thickening in the walls of the heart. He had grown enormously stout, principally from fatty deposit. Had he remained in Minnesota I see no reason why he might not have lived until this time, but the heat-match having been applied to the tinder, softening commenced, and, in spite of his return to Minnesota, went rapidly on, causing his death in a few months.

I recall the cases of two boys, one a patient of Dr. Yeates, and the other of Dr. Van Bibber, of Baltimore, with well-marked tuberculous meningitis, characterized by the concave-bowed abdomen, *tache meningite*, etc., who happened, after this disease had set in, to contract typhoid fever, from which one recovered with absolute deafness, and the other with epilepsy which he still has, accompanied, at intervals, with homicidal mania, but except for the supervision of typhoid fever it may be questioned whether, even on these terms, their lives could have been saved.

Supposing that there was less phthisis in England and Wales after than before the greatest epidemic of typhoid that has happened since Dr. Armstrong's times, and which caused between the years 1869 and 1875 as many deaths as an invading army might have done, I wrote to the registrar-general,<sup>1</sup> who kindly sent me the following answers to my queries: "The deaths referred to phthisis in England and Wales were 52,270 in 1869; 54,281 in 1870; and 53,376 in 1871; they were 51,775 in 1876; 51,353 in 1877; and 52,856 in 1878. Having regard to the increase of population, the recorded mortality from phthisis was lower in the three years, 1876, 1877, 1878, than in the years 1869, 1870, 1871.<sup>2</sup> When I get the clarified returns from the particular districts in which typhoid fever was most prevalent, there is not a doubt that the figures with regard to the relative frequency of phthisis in these years will be still more marked.

#### FOLLICULAR DISEASE.

Having endeavored to show that occurrence of the phenomena grouped under the classic name of typhoid

<sup>1</sup> I regret not being able to refer to a priceless contribution to general medicine, contained in a paper read before the International Medical Congress, by Dr. Ernest Hart. It is now in the printer's hands, and will shortly appear. The volume will contain reference to seventy-one epidemics and epidemics that have happened in Great Britain, with carefully analyzed details and tabular statements relating to them.

<sup>2</sup> From W. Ogle, M. D., superintendent of Statistical Department.

fever, and numerous other synonyms, will, by abolishing the tuberculous diathesis, not only ward off and prevent phthisis, but arrest and shunt on to the track of convalescence incipient and progressing cases of this malady, it may not be out of place here to state that, in my belief, this great constitutional reformer, typhoid disease, cures also chronic inflammation and hyperplasia of the mucous follicles in whatever part of the inner lining membrane they may be seated. The diseases caused by this pathological condition of the mucous follicles, and named according to locality, facial, follicular disease — stomatitis, follicular pharyngitis, granular, or granulated sore throat, follicular gastritis, or dyspepsia, or follicular enteritis, follicular colitis, etc., I have been accustomed to regard as amongst the *opprobria medicinae*, since this morbid condition of the follicles exists in many cases from infancy to old age, and I have never seen the chronic form of them cured by therapeutic means of any sort, but have only seen them palliated, or for a time improved by the use of certain agents, notably by the mild sulphur waters. But by typhoid fever I have repeatedly found the enlarged mucous follicles, wherever situated, reduced to their normal size, and brought back to a healthy performance of their functions.

## REMARKS.

My desire in writing the preceding has been to suggest: —

(1.) The importance of intestinal inoculations with the object of inducing typhoid fever and thereby preventing a recurrence of this disease in after life and to prove that by this method alone, once successfully applied, the prophylaxis of continued fever, typhoid disease, is rendered complete, and that typhoid fever would indeed appear to be a more powerful alternative and deterrent than any other known means, repairing in many cases errors of constitution growing out of morbid consanguinity.

(2.) That the rôle of phenomena in typhoid fever once experienced annuls tubercular diathesis, and is the only trustworthy guarantee against phthisis.

(3.) That in mild incipient cases of phthisis the tuberculous diathesis is subdued, and the disease arrested by the supervenience of typhoid fever, and therefore, to induce the latter, intestinal typhene inoculation would appear in many cases to be the only remedy for consumption.

(4.) Since most members of many families suffer more or less all their lives with follicular diseases, typhoid infection or inoculation, as a means of radically restoring the mucous follicles everywhere to a healthy performance of their functions and thereby preventing or abolishing the diseases in question, would seem to be of the greatest importance.

Instead, therefore, of waiting, as I have done, a lifetime for rare coincidences where this supervening curative and vicarious disease arriving arrests or supplants the otherwise irremediable maladies, as well as for the concurrent ideas of others in regard to its prophylactic and therapeutic powers to germinate, would it not be well that physicians so situated as to be able to follow the investigation scientifically should, with contagion procured from the mildest cases to be found, institute a series of typhoid inoculations in the young for

<sup>1</sup> The significant names given to this disease by Andral because its seat is in the mucous follicles, and not in the free mucous membrane in which they are everywhere embedded.

comparative study? From the dealer in infected milk a hint may be taken as to the method of inoculation.

In stationary France, with prolific Germany on her border, population is getting to be an economic question, not less important to the future of the Gallic race than agriculture and manufactures, and as the lives of men are coming to be considered as valuable as those of sheep and silkworms, it is to be hoped that M. Pasteur, with his rare genius and extreme ingenuity, will take an interest in the work by cultivating in milk or chicken broth the inoculable contagia of typhoid fever, and it would be well if Dr. Creighton and Professor Eberth, of Zurich, would devote their time and talents to the same object, in order that the inoculable *materies morbi* of continued fever may be had in all places, at all times, and in the most proper and convenient form. Very truly yours,

T. H. BUCKLER, M. D.

PARIS, December, 1881.

### RUPTURE OF GALL-BLADDER (?) AND DISCHARGE OF BILE THROUGH THE LUNG.

MR. EDITOR. — Permit me to briefly report an interesting case which occurred recently in my practice.

February 2d, I was requested to see Samuel V. —, a young man of robust appearance, a laborer. Found him with a temperature of 103° F., pulse 128, and a very dark-colored skin. There was extreme tenderness in right hypogastrium, with considerable swelling, and dullness extending above the costal cartilages.

Deep percussion revealed the left border of the liver about five inches to the left of the median line. The gall bladder could also be felt greatly distended. The treatment was expectant.

These conditions were unchanged for the five following days, the stools being white and urine containing bile. There developed on the 7th a dry, hard cough, and on the 8th he began to expectorate large quantities of *bile*, as proved by the nitric acid and Pettenkoffer's tests. He was delirious nearly all the time, and evidently sinking very fast.

On the 10th the sputa were normal in color, and an injection brought away a healthy though rather dark passage from the bowels.

After this the convalescence was very rapid, and at present, 14th, he is about the house, though much enaciated.

Very truly yours,

A. W. PARSONS.

BRAINERD, MINNESOTA, February 14, 1882.

### TYPHOID AND MALARIAL FEVERS IN CONNECTICUT.

THE report of the Secretary of the State Board of Health of Connecticut for the month of December makes the following statements in regard to typhoid and malarial fevers: —

The increased frequency of typhoid fever, noticed recently, continued well into December, as seen by the deaths from that cause reported in the table. Typhoid fever is also reported from Plainfield and vicinity, a few cases fatal; also, from Watertown, none fatal, but prevalent during the fall; a few cases from Unionville, one fatal; also in Salisbury, Suffield, Naugatuck, and

several other places, but not usually of a severe type nor very frequent, five or six cases at the most in any one place.

Malarial fevers are reported as having invaded new territory to the eastward and northward. The cases in Providence, R. I., were mentioned last month, but since then I have learned of its existence in Thompson, the extreme northeastern town of the State bordering on both Massachusetts and Rhode Island. The mortality returns also report deaths from several towns in Windham County. What is extremely singular is its method of progress. For some time it has maintained about the same eastern boundary line, slowly advancing, but now it advances by leaps, as it were, and settles down in the centre and extreme limits of the hitherto uninvaded part of the State. This advance by leaps, *per saltum*, to be technical, rather militates

against the theories more commonly accepted, as there is nothing peculiar in the localities selected to induce the appearance or stay of malaria. The marsh miasm theory has indeed received some pretty hard thwacks lately. The open, mild winter has favored the existence and spread of malaria, which is often found upon some hill-top as well as in the valley. The invasion of the State threatens to be complete at no very distant period. There is one consolation. It is fading out in many of the older haunts to quite a considerable degree, the type is not so well defined, the intermittent and even periodic character grows fainter, and what is called the mongrel malarial fever becomes common. The re-appearance of typhoid fever is also in the same line. Malarial diseases are reported as prevailing extensively in Fairfield County and in some parts of Litchfield County.

## REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 11, 1882.

PELVIC EFFUSIONS AND THE IMPORTANCE  
OF THEIR EARLY RECOGNITION, WITH  
REFERENCE TO TREATMENT. REPORT OF  
ELEVEN CASES.<sup>1</sup>

BY G. D. LYMAN, M. D.

A FEW months since I reported to the American Gynecological Society one hundred and forty-six cases of pelvic effusions, of which forty-one resulted in abscess. These cases occurred at the Boston City Hospital during the preceding five years. During the last quarterly term of service, beginning October 1, 1881, eleven additional cases came under my charge, of which two were of puerperal origin, two were clearly sanguineous effusions, hematoceles, resulting in abscess, and the remainder were effusions the exact character of which can be surmised only from the records of them given below, some probably hemorrhagic, but most of them either plastic exudations or simple serous effusions from pelvic cellulitis or peritonitis, for, as in many hospital cases, an exact positive differential diagnosis is often impossible, the antecedents obtainable, especially if they be at all chronic, being generally vague and indefinite, rendering it impracticable to ascertain whether a certain mass of pelvic effusion was of serous or sanguineous origin, unless by aspiration, or otherwise, the contents can be submitted to ocular examination.

As these cases were most of them in the wards at the same time, and comprised examples of acute recent effusion, both serous and sanguineous, older chronic exudations, and puerperal cases, a rare opportunity was afforded the students to learn the causes and progress, the diagnosis and treatment, of this common affection from its very inception, as well as its various results of rapid absorption when recognized and treated early, or, when not coming under treatment until a later period, of plastic exudation with slower absorption, or, finally, suppuration and evacuation artificially or by spontaneous rupture into the bladder, groin, etc.

These different varieties of pelvic effusion may all, of course, result in suppuration, and become true pelvic abscess, but with reference to both prognosis and treatment, it is practically important to have the diagnosis as accurate as possible in any given case; a simple serous effusion, for instance, even though large in amount, ought to, and in the majority of cases does, recover rapidly, leaving the pelvic organs in a healthy condition for future service. This very fact indeed, is, I believe, a fruitful source of error in diagnosis, many a case of pelvic trouble, with pain, dysuria, rectal tenesmus and metrorrhagia, being attributed to cystitis, dysentery, or metritis, and the urgent symptoms being relieved no farther directions or attention is given to the sequelæ, until they come under observation, perhaps long after, as the result of some irritation which might have been avoided had the true nature of the case been recognized. A sanguineous effusion is often, likewise, rapidly absorbed, but as a rule not so rapidly as the former, and under unfavorable conditions, which are not anticipated by correct diagnosis, they are even more liable to suppuration, the earliest advent of which should be diligently watched, and met with surgical interference.

Puerperal cellulitis, on the contrary, either as the direct result of injury or from septic absorption after labor, is always a more tedious and grave affair in its immediate consequences, and certainly not less so in the ultimate condition of the sufferer when the discharge has ceased, as shown by the displacement of organs, the firm adhesions of the pelvic tissues, inclosing here and there masses of exudation, which, under the obvious manifold conditions of irritation to which every woman's pelvis is liable, become the focus of renewed suppurative action. Indeed, it is questionable whether a woman ever recovers entirely from the effects of a bad pelvic abscess, until, at any rate, after the menopause.

It is quite too common to treat these cases as tending always to ultimate recovery, surgical interference being declared not only unnecessary, but even unwise. If by recovery is meant the cessation of suppuration, after a time,—almost always greatly protracted,—and the ability of the patient to resume in some measure her ordinary avocations, the statement may, perhaps, be accepted, but before pronouncing a patient well after one of these abscesses, it would be worth while to get her subsequent history for a few years. Every one who has had occasion to see much of these cases knows very well, not merely their liability to recurrence so long as any plastic exudation remains, as it almost invariably does in greater or less quantity for long periods, but the tedious history of months, often years, of pain, irritable bladder and rectum, painful coition, menorrhagia, metrorrhagia, and irremediable uterine displacements, to say nothing of the multiform reflex disturbances, which render existence almost a burden. Cases of spontaneous opening into the bladder or rectum often close with comparative comfort to the patient for long periods, only to reappear again under any unusual excitement. It is not in these cases so much a question of death,—although no mean percentage, especially of the puerperal variety, do result fatally,—but it is a question whether, as the result of early and accurate diagnosis, we may not much more often give such prompt relief as to preserve the normal relations and integrity of the parts, and so avoid this protracted discomfort and invalidism. We do not treat other affections, much less important, after this expectant method. It would seem quite as rational to leave a bad mammary abscess to burrow on for months without any regard to the ultimate integrity of the gland, the protracted suffering, or the constitutional exhaustion.

If the great frequency of pelvic peritonitis, cellulitis, and hematocele were more generally recognized, and an early and discriminating diagnosis obtained before they had reached the period when such diagnosis becomes impossible, a larger proportion would be cut short before the stage of suppuration, or, having reached that stage, the damaging results to the pelvic viscera could, by early evacuation, be anticipated.

In some of the cases given it will be seen that early recognition and treatment were followed by prompt recovery in the proper meaning of that term. In others with an older history, and with large plastic exudations tending evidently to mischief, treatment was effectual in averting suppuration, affording a marked contrast to still others where spontaneous openings had occurred more than once in a period of years, and which, if more promptly recognized, might possibly have been prevented.

<sup>1</sup> Read before the Boston Obstetrical Society.

I do not assert, of course, that every case is amenable to arrest by surgical interference, for often neither fluctuation nor any signs of suppuration are discoverable to the most vigilant observation, but it is none the less true that many more occur where it is impossible to doubt that opportunities for relief by aspiration are missed because not carefully sought for. I would even go farther, and urge that where any reasonable doubt even of suppuration exists, aspiration be resorted to, especially as it has often happened in cases of failure to reach pus that the irritation of the needle has stimulated absorptive action in the indurated mass.

The causes, location, pathology, and diagnosis of these various pelvic effusions have been so exhaustively treated since 1850 (before which time little was known with certainty), that I will not trespass to any extent upon your time by discussing them. Bernutz, Aran, Nélaton, Voisin, Scanzoni, Virchow, and others have written freely, some of them exhaustively. Many valuable contributions also have been made by English and American authors, which are familiar to all interested in the subject, and I will therefore content myself with a short summary of points generally recognized as most important to bear in mind, especially as to diagnosis and treatment.

The difference so much contended for between phlegmon or thrombus (outside the peritoneum) and hæmatocele (within the peritoneum) need be alluded to only so far as to state that the former, that is, the extra-peritoneal sanguineous effusions, generally obtain in puerperal cases, tending to external openings, as the groin, thigh, etc. — the latter, or intra-peritoneal, where suppuration follows, more often seek an outlet internally through the vagina, bladder, or rectum, or even, in rare cases, burst the adhesions above and escape into the abdominal peritoneum, menstruation playing a large part in their causation, though it is now well proved that blood may be extravasated at the catamenial periods into the cellular tissue beneath and external to the peritoneum, behind the uterus, or into the broad ligaments.

Pelvic peritonitis from defective or interrupted excretion is very common, hæmatocele from the same cause rare, so that too much stress is not to be laid in the diagnosis upon the fact of a coincidence between the catamenial period and the formation of the tumor. Bernutz<sup>1</sup> asserts that this would lead to error three times out of four, the reverse being true of "metrorrhagic hæmatoceles," as he calls them, where the flow from the uterus and the rapid formation of a tumor projecting into the abdomen above and the pelvis below, with the coincident symptoms of acute peritoneal irritation, are wholly unlike the slower formation of serous effusions and plastic exudation.

Hæmatoceles are rare in puerperal cases at term, pelvic peritonitis and cellulitis common, and usually terminating in suppuration.

In hæmatoceles the anæmia, the collapse, the rapid development, are usually characteristic as compared with the latter, the contrast modified by the rapidity with which the blood is poured out, that, for instance, from a ruptured tube or varix being of course more striking than the slower effusion from ovarian congestion or peritoneal hæmorrhagic exudation. Still, the diagnosis in those cases of pelvic peritonitis with effu-

sion coexisting with metrorrhagia, will necessarily cause confusion which only careful observation of the order of the symptoms will clear up, especially the inversion in the order of their occurrence in the two cases respectively, hæmatoceles from any cause being accompanied first by the effusion and pain, then a rapid development of the tumor, reaching, in extreme instances, to and beyond the umbilicus, thirdly, anæmia, possibly collapse, and lastly the development of febrile symptoms, while, on the contrary, in the effusions from peritonitis and cellulitis we have first the febrile symptoms, then a gradual and more limited effusion, generally but not always confined to the pelvis, an absence of anæmia and collapse, and lastly the ordinary signs at a later period, of suppuration, should such a termination not be averted.

The difficulty of obtaining the relative order of the symptoms in many hospital cases, arising from lack of intelligence or of memory in the patient, and especially where the disease is already of some duration, renders, as I have already said, accurate diagnosis frequently impossible. In this connection it should not be forgotten that the two affections may coexist. Bernutz gives such cases. Cases also occasionally arise where neither menstrual irregularities, pain, the rapid development, the vaginal touch, the extension above the pubes, etc., can be wholly relied on. Voisin (de L'Hæmatocele, page 180) gives the history of such a case in which Nélaton himself mistook a purulent collection from peritonitis for a hæmatocele. See, also, Bernutz on diagnosis of pelvic peritonitis and hæmatocele. (Vol. II.)

The results obtained from vaginal examination, also, are entirely unlike in the two cases. In hæmatocele the mass is reached often with difficulty, is more apt to be central, — yields at first a doughy, boggy feeling, and is often free from pain when touched, while in pelvic peritonitis, on the other hand, the vagina is hot, the swelling excessively sensitive, more lateral, dense and inelastic, and rarely rising above the pubes, being limited by the peritoneal adhesions resulting from the initial inflammation.

In hæmatocele menorrhagia is usual, especially in the earlier stages, and the tumor, after absorption commences, is said by Voisin<sup>2</sup> to decrease markedly with each monthly period; serous or plastic effusions, on the contrary, though metrorrhagia is very common in them, are neither influenced at first, or affected subsequently, by the monthly flow, which often recurs normally throughout.

I am quite aware that much of the foregoing is perfectly familiar to most of those present, but I have thought that in view of the recent discussion in this Society of the subject of puerperal pelvic abscess, these cases and the remarks suggested by them might be of sufficient interest to justify their presentation. I wish again to reiterate that, notwithstanding the objections made by some of the highest authorities, an early exploration of such effusions when suppuration is impending is, in my judgment, not only advisable when practicable, but is absolutely demanded for the ultimate well-being of the patient. I repeat that it is not so much a question of death as it is a question between partial recovery with all the organs in an abnormal condition, and entire restoration anatomically and functionally. The let-alone policy certainly would not be thought justifiable in parallel surgical affections,

<sup>2</sup> Voisin de L'Hæmatocele, Paris, 1860, page 164.

examples of which will readily enough suggest themselves.

**CASE I. Acute Effusion following Injury; Probably Sanguineous, with Secondary Local Peritonitis.** — J. P., thirty-three, married, entered hospital December 14th, never had children or miscarriages, menses always regular. Three weeks since, and one week after cessation of menses, she fell down stairs. This was followed by pain in standing or walking. A few days subsequently she had a rigor and has since had several chills, but neither vomiting or fever at the time. Defecation painful, micturition frequent, urine thick and reddish, anorexia, headache, insomnia, and slight bloody leucorrhœa since injury. Says the pain grows constantly worse. Vaginal examination shows a large effusion to the right of the uterus. Cervix not displaced, but uterus not movable. Under fomentations, rest, and opiates, she was made comfortable, and in two weeks (December 31st) she was nearly free from pain, the effusion rapidly diminishing, and the uterus more movable. No signs of suppuration.

January 15th. Nearly well of the pelvic trouble and remains in hospital for chronic pulmonary disease.

**NOTE.** The normal position of the cervix with such an effusion is noteworthy, and also the lateral position of the tumor. The reddish urine was probably from admixture with the vaginal discharge. From the early history dislocation of the uterus might have been anticipated but nothing of the kind was found.

**CASE II. Hematocoele; Rapid Absorption.** — S. W., age twenty, entered October 18th, married one year, never pregnant, menses always regular and free. Has been sick in bed two weeks. Without any known cause was attacked with sudden pain and flowing, one week after cessation of catamenia. The hæmorrhage continued copiously for a week, and then ceased, but the pain still continued, extending above the pubes — has pelvis tenesmus, increased by micturition, has chilly sensations but no positive chill, — has never had such an attack before.

October 18th. Vaginal examination shows the uterus to be fixed, the cervix wedged against the symphysis and a mass of effusion behind the uterus extending mostly to the right. Under treatment this rapidly absorbed and on the 31st a collar-like cellular infiltration, hard and free from pain and encircling the cervix, was all that remained.

November 2d. Was discharged at her own request with such cautions as to the slight induration remaining as seemed necessary.

**CASE III. Pelvic Peritonitis.** — C. H., twenty-two, married, entered November 3d, one child eleven months previously, menses always regular, no leucorrhœa, no miscarriages. Five months ago and six months after her labor, wet her feet while menstruating — had menorrhagia, pain in pelvis and down right leg with vomiting, abdominal tenderness, and leucorrhœa, but neither rigors nor dysuria — was confined to her bed for a week, after which was up and about but unable to work. Three weeks before entrance took to her bed again with a renewal of all the symptoms and an increase of the fever and pain. The last attack came on during a menstrual interval.

November 4th. Vaginal examination revealed an effusion in Douglas's pouch extending down the recto-vaginal septum with a deep sulcus between it and the cervix. The uterus fixed, some tenderness in the

right groin, but no hardness above the pubes. Uterus three inches deep, the sound passing to the right.

November 12th. Effusion much diminished and the pain has ceased.

November 13th. Patient sat up yesterday and today has had two rigors, continuous vomiting and severe epigastric pain.

November 16th. Universal tenderness, and micturition painful.

November 18th. Much improved, the pain has ceased, and the pulse and temperature are normal.

November 22d. Still improving, the effusion is absorbing rapidly, no tenderness, and uterus more movable.

December 6th. Effusion nearly gone. There remains a small ridge to the right of the cul-de-sac and on the left a dense, hard ridge extends from the side of the pelvis to the junction of the cervix and body.

December 10th. Indurations less marked, and the patient, feeling well, was discharged at her own request after being warned of the danger of relapse.

**NOTE.** If the first attack, six months after her labor, had been recognized the recurrence of the disease might have been averted by proper treatment. It was possibly connected with the puerperal antecedents, though the enlarged uterus may have been very well attributable to the long-continued pelvic congestion.

**CASE IV. Pelvic Peritonitis; Obscure History; Probably Sexual Excess.** — C. F., twenty-five, single, entered December 24th, had one child at sixteen, labor natural. Has been sick a month with pain in back and bowels, mostly on left side and down the left leg. No rigors, no dysuria, no abdominal enlargement, some tenderness on pressure; knows no cause.

December 26th. Vaginal examination reveals a lacerated cervix and a mass behind the uterus the size of a large egg, reaching up into the hollow of the sacrum. Under fomentations, vesication, and applications of iodine externally, she gradually convalesced; remained in hospital for convalescence until February 4th, when she was discharged well.

**CASE V. Pelvic Peritonitis, of Long Standing and Recurrent; Probably Induced Originally by Abortion.** — H. B., forty-five, a widow; entered December 14th, menses at sixteen, always regular but painful; had two children, and two abortions induced by herself "with an instrument given by a doctor." Last pregnancy sixteen years ago; had an attack like the present seven years ago, otherwise well until three weeks since, when, two weeks after catamenial period, she took to her bed with severe abdominal pain extending down the thighs, which came on suddenly after a hard day's work in washing; no dysuria, no vomiting, chilly sensations not amounting to rigor, constant flowing for past two weeks.

December 15th. Vaginal examination shows the mucous membrane of the posterior wall ridged and hypertrophied and extending back for two inches, resembling an enlarged urethra. Rectal examination shows no pouching of the rectum, cervix uteri pushed forward by a large mass in posterior cul-de-sac, fundus retroverted, sound entering two and one half inches. The uterus was gently curetted, removing clots and some portions of mucous membrane, and causing slight pain; iodine applied to cavity. The flowing continued slightly up to the 24th, the time for her regular period, when it ceased entirely, instead of increasing.

December 31st. No recurrence as yet of the menstrual period. She is much improved and the effusion is rapidly absorbing.

January 4th. Mass reduced to size of an English walnut. She remained for convalescence until February 4th, when she was discharged well.

CASE VI. *Pelvic Peritonitis, followed by Cellulitis and Chronic Cystitis.* — M. McC., thirty-one, single, entered August 17th, with history well marked, of peritonitis caused by cold at the menstrual period a year previously. Gave up work three months before entrance. Complaints of lumbar pain extending to thighs, vaginal heat and leucorrhœa and irritable bladder. The urine contains pus. Pressure above pubes causes pain.

October 8th. Vaginal examination shows a vaginal os uteri, the uterus freely movable and retroverted; remains of old cellulitis shown by several deep firm ridges stretching across the posterior cul-de-sac.

November 20th. Patient has decidedly improved during the six weeks since last date, under hot douches, counter-irritants, opiates, bladder injections, etc., but she is very nervous and irritable, complaining still at times of dysuria. The hard ridges in the cul-de-sac having become much softened, attempts to replace the fundus uteri were cautiously made, but she was unable to bear any form or size of pessary, or even cotton tampons, and after repeated trials they were discontinued, as they caused too much pain and general discomfort. She left January 9th, improved.

NOTE. A well-marked instance of chronic cystitis, uterine dislocation, neuralgic pain, and permanent injury to health from pelvic peritonitis, suffered to continue for a year without proper treatment.

CASE VII. *Hæmatocele; Pelvic Peritonitis and Cellulitis; Extensive Effusion, either Serous, Sanguinous, or both.* — L. C., aged twenty-seven, widow, entered August 4th; has had one child and two miscarriages; menses began at thirteen, always painful but regular; has been sick for two or three months, with steady pain in back and through the bowels; almost continuous metrorrhagia, sometimes offensive; constipation and headache; at entrance pulse was 124, temperature 100° F. A hard nodule was found on the anterior lip of the cervix, bleeding easily. For ten days after entrance had diarrhœa. She continued with constant pain in lower abdomen, the metrorrhagia apparently diminishing, until October 2d, when, upon examination, I found the cervix pointing forward and to the left; behind the uterus, separated from it by a deep sulcus, a large, hard mass of effusion extending from the left to the right side of the uterus (but mostly on the right), and rising into abdomen nearly to the umbilicus.

FIG. 1.  
The Amount of Induration as shown by Abdominal Palpation

(See diagram.) Uterus fixed, no fluctuation bimanually, nothing between uterus and bladder. Could bear but little pressure in supra-pubic region. She continued with more or less of pain, vomiting, and dysuria until the 20th, when, on vaginal examination, a diminution of the effusion on the left side was noted, and also of the supra-pubic enlargement.

November 22d. During the four or five weeks since last report has had some re-

lief from fomentations and douches and free use of opiates; has had chilly sensations, but no rigor; no other evidence of suppuration. Vaginal examination now shows some farther diminution in the posterior mass and a slight extension of the induration to the front of the cervix. No fluctuation or softening.

December 7th had a recurrence of vomiting and severe pain. Vaginal examination now shows the left side to be comparatively free.

December 15th. The house officer was called during the night, and found her over the foot of the bed in a doubtful condition of convulsion; this was considered to be hysterical, and due to the free use of opiates, which from this time were much diminished. Three days later (the 18th) a surprising diminution of the effusion was found, and by the 23d only one very small spot of hardness, on the right of the uterus, remained. Being free from pain, and able to sit up, was allowed to go home.

NOTE. The hardness, the lateral position in the pelvis in the early stages, of the larger part of the effusion, would indicate peritonitis, and especially the late occurrence of cellular induration anterior to the uterus; but the metrorrhagia, the abdominal extension of the effusion, and the ultimate rapidity of absorption are more characteristic of hæmorrhagic origin, though there was no marked anæmia. The rational supposition, it seems to me, is that the effusion was originally sanguineous, and that the inflammatory action was secondary.

CASE VIII. *Endo-Cervicitis and Chronic Cellulitis; Menorrhagia.* — L. C., twenty-eight, single, entered August 25th. Has been sick a year with dysmenorrhœa, menorrhagia, metrorrhagia, and dysuria. Examination revealed a hard, irregular mass in the posterior cul-de-sac, movable with uterus. Catamenia have been always irregular and painful, with a free flow lasting ten to fifteen days; has leucorrhœa, occasional headache, and vomiting, and has lost flesh; abdominal tenderness, aggravated by stooping or defæcation. Has never been pregnant.

October 2d. Vaginal examination reveals a small mass of induration, not tender, high up in Douglas's pouch, a general congestion of the cervix and upper part of the vagina, with the cervical mucous membrane, so far as visible, roughened and congested. Patient very nervous. The sound in the cervical cavity induced extreme pain.

November 1st. The effusion very much diminished. The sound still causes extreme pain.

November 12th. Menses came on and lasted but one day.

December 4th. Much improved. Now menstruating again, but less abundantly and with less pain than formerly. She continued improving under fomentations, douches, and scarifications of cervical canal until the 15th, when the effusion and the cervicitis had nearly disappeared, the fundus being slightly displaced by the adhesions latero-posteriorly.

December 19th. Well enough to be up and about, and was discharged at her own request.

CASE IX. *Pelvic Hæmatocele; Suppuration; Artificial Opening through Posterior Wall of Vagina; Sac ruptured by Iodine Injection; Recovery.* — H. O'C., thirty-two, married, entered December 18th. A clean, healthy-looking woman and mother of four children, the last four months old. Three months ago, during the first menses after her confinement, she was, without any traceable cause, suddenly seized with se-

vere cramp and pain extending through the pelvis and loins, followed immediately by a rigor. Two days later had severe vomiting, and subsequently repeated rigor, with excessive abdominal tenderness and painful defecation. Had no dysuria for first four weeks. Continuous menorrhagia until three weeks before entrance. Has never discovered any supra-public enlargement. Pulse 104; temperature 100.6° F. The cervix was found far forward and fixed; a large boggy, fluctuating mass, not sensitive, was found behind the uterus and pressing upon the posterior vaginal wall. A large trocar gave vent to one ounce of thick, bloody, offensive fluid, mixed with small coagula. Carbolic water was injected until it returned clear. The tumor was but slightly reduced. The following day she was perfectly comfortable, with a free, colored discharge.

December 20th. Again washed out.

December 22d. The opening was enlarged to an inch with a metrotome, and offensive coagula removed; daily injections ordered.

December 26th. The washings still bring away much offensive matter. The injections cause no pain, and she is in every way comfortable.

December 30th. Discharge much less offensive and nearly colorless. Depth of sac reduced to one and a half inches.

January 3d. Healthy pus only discharged. Tincture of iodine, one to two drachms, injected without pain.

January 11th. The discharge not diminishing, iodine was again injected, but was now followed instantly by great pain and collapse, feeble pulse, cold extremities, and sweating. The pain was most severe over the epigastrium, though she complained of burning throughout the abdomen. Stimulants, hot fomentations, and morphia subcutaneously soon gave relief, though she had three slight rigors during the day.

January 12th. Complains a little of her stomach and of a "bad strange taste" in her mouth, but slept fairly, and is perfectly comfortable. No fever.

January 17th. The orifice was stretched with sound to prevent closure. The discharge soon ceased almost entirely, no induration remaining, and she left, well, January 23d.

NOTE. In this case the opening was made just as suppuration was commencing. If left to itself it would probably have discharged into the rectum and been followed by a long and exhausting pelvic abscess, with cellulitis, plastic exudation, and the usual sequelae of displaced and adherent organs. This is the second instance in which I have known injections of the sac to be followed by symptoms of rupture into the abdominal peritoneum. In both iodine was used, late in the disease and after repeated previous washings with water, alone or carbolized. In neither instance did any serious result follow, though it must be confessed that the symptoms were sufficiently alarming at first to impress one with the necessity of extreme caution and gentleness in such cases.

CASE X. *Chronic Puerperal Pelvic Abscess following Labor Sixteen Years ago; repeated Acute Attacks, with Openings into Bladder and Vagina.*—F. H., forty-four, widow, entered September 6th. After delivery by instruments sixteen years ago she had "inflammation of the bowels," probably cellulitis. About every six months for the past thirteen years she has had attacks of rigors, with great pain in the pelvis,

and other symptoms of pelvic inflammation, lasting for ten days or more. She was in the hospital three years ago, her history at that time being one of both vaginal and bladder opening. Since that time has had no more "leucorrhœa," which had previously been abundant at times, and no more of these recurrent attacks until the present. The menopause occurred twelve months since.

October 2d. A dense band of cicatricial tissue is found stretching across the vagina in front of the cervix, but not obliterating the passage. Some inflammation and thickening of the vaginal vault, but no positive induration is discoverable, either by vaginal or rectal examination.

October 8th. A rigor occurred, followed by vomiting, abdominal pain, and irritable bladder, with a large quantity of pus in the urine. This acute suppurative process, with abundant discharge of pus from the bladder, continued for many weeks. The symptoms, however, all gradually subsided, and she left the hospital November 14th, much relieved, though the urine still contained some pus.

NOTE. This case is a good illustration of the miserable condition of many patients who are supposed to "recover" from pelvic abscess. Whether the vaginal cicatrices were significant of previous openings into the vagina, or whether they resulted from injury at the time of her labor and were the *point de départ* of cellulitis and abscess at that time, can only be conjectured. The "leucorrhœa" was possibly pus from an abscess opening formerly into the vagina.

CASE XI. *Recent Puerperal Pelvic Abscess, opened in the Groin; Bronchitis, etc.*—A. D., aged twenty-one, married, entered September 21st. Nothing unusual in her menstrual history; has been married two years; has had one miscarriage, and one month before entrance was delivered at full term, leaving her bed in two weeks feeling well. Directly on getting about, however, was attacked with vomiting, rigors, diarrhœa, dysuria, and abdominal pain. The vomiting still continues. Temperature 102° F.; pulse 120. The lochial discharge ceased a few days before entrance. Examination shows absolute rigidity and solidification of the pelvic roof, the uterus immovable, and the abdomen tender in the supra-public region. She soon began to reject all food and stimulants, and a small bed-sore appeared on the sacrum.

October 6th. The vomiting and great prostration have continued until date, and she has been nourished by enemata. To-day she is able to retain one teaspoonful only at a time.

October 8th. Abdomen softer, but still very tender.

October 13th, a large slough half an inch thick and nearly two inches in diameter was removed, leaving the sacrum exposed and an extensive, deep, undermined ulcer, four to five inches in diameter. She has large aphthous patches on the tongue and cheeks, involuntary dejections, and retains nothing but small doses of beef extract. For two days has had severe inflammation of the throat, with aphonia.

October 10th. Though the abdomen was very tender, by gentle palpation the induration was traced above Poupart's ligament on the left side one third way to the umbilicus. (See diagram, Figure 2.)

October 15th. Able for the first time since October 1st to make a vaginal examination. A large mass was now found filling the left pelvis and extending above Poupart's ligament a third of the way to the

umbilicus, hard and resisting, and with no signs of fluctuation discoverable, but on the 17th a doubtful spot above Poupart's ligament was opened with the bistoury, and yielded a small amount of fetid pus. This opening was poulticed, all pressure being carefully avoided.

FIG. 2.

Situation and Extent of Effusion as shown by Abdominal Palpation October 10, 1881.

October 18th. More comfortable. Abscess discharging slowly. Has now cough, with abundant sonorous and sibilant râles. She, however, continued to improve for a week, when she had a relapse of vomiting, caused by improper food. From this time improvement was uninterrupted. After discharging freely the opening closed, and the sac not refilling, December 4th was able to sit up.

December 31st. Uterus was found to be movable, with very slight posterior adhesions, no remains of induration or swelling to be found, and the large sacral sac nearly closed. She was allowed to remain in the hospital for a time to regain her strength. When able to leave her bed she found herself with partial loss of both motion and sensation in the lower extremities, which it required nearly two months to recover from, probably from granular muscular degeneration after such protracted high temperature.

NOTE. The suddenness of the attack when apparently well and two weeks after a normal confinement would suggest a hemorrhagic origin, but whether hemorrhagic or septic the early pointing and evacuation doubtless saved her from extensive consolidation of the pelvic tissues, and probably from much future trouble, as there remains no discoverable induration by external or internal examination in the lateral regions of the pelvis. The uterus is freely movable, the posterior adhesions being too trifling to cause any interference.

#### REPORT OF THE COMMITTEE ON METEOROLOGY AND EPIDEMICS FOR THE YEAR 1880, IN PHILADELPHIA.<sup>1</sup>

BY RICHARD A. CLEEMANN, M. D.,  
Member of the Board of Health of Philadelphia.

*Temperature.*—The mean annual temperature of the year 1880, as calculated from the monthly means, was 54.6° F. (Table A), or 1.7° F. above the average for the nine years 1872-1880: the year was, then, taken as a whole, a warm one; indeed, during these nine years there was but one for which a higher mean temperature was recorded, 1878, when 54.7° F. was attained (Table B).

The first six months of the year, and September, each exceeded their respective averages of mean temperature during nine years. January, with the mean reading of the thermometer for the month at 41° F., went beyond its average as much as 8.7° F., and the mean of 39.1° F. for February was 6.1° F. above its average; so that the winter was wonderfully mild for

this climate. A greater warmth of the spring was not so marked, except at the close, the monthly means of temperature in the several months being for March 39.6° F., for April 52.4° F., and for May 68.8° F., or respectively .7° F., 3.3° F., and 6.9° F. above their averages. So high a degree of heat in May was very exceptional, the mean temperature of the month in no one of the previous eight years rising within 7° F. of this value. On the other hand, the months in the latter half of the year, with the exception of September, already mentioned, were each of lower temperature than usual, December being very cold. The fact that June, marking a mean of 73.8° F. exceeded its average 2.3° F., while July, recording 75.6° F., and August 72.8° F. were respectively 1° F. and 6° F. below their means, led to the summer being more equable than we are accustomed to find it. The fall, on the contrary, showed a greater variation in temperature between the months than is common, the 67.9° F. of mean temperature of September being 1.6° F. above its average, while the 55.1° F. of October and the 40.5° F. of November were respectively .9° F. and 2° F. below their means. The mean temperature of December, 28.6° F., is as much as 5.4° F. below its average for nine years, and is, with the exception of that for 1876, the lowest recorded for the month during that period.

The range of the thermometer during the year was through 101° F. of temperature; from 96° F. recorded in May to -5° F. noted in December. The month of May was distinguished by the widest variation in temperature, the thermometric range being through 60° F., and August by the narrowest, 34° F.; between these two the other months came in the following order: July with a range of 35° F., September of 41° F., June of 43° F., January of 44° F., October of 47° F., April of 52° F., February of 55° F., March, also, of 55° F., December of 57° F., and November of 59° F. This is nearly the usual sequence of the months as far as those of the summer and September are concerned, this season being the most equable of the year in Philadelphia; the absence of extremely cold weather in January, however, has given it an uncommonly high place in the list, while the warm spring has done a like thing for April; on the other hand, the premature approach of summer in May carried the range of this month much beyond its usual extent, and the early winter had a similar effect upon November. No frost was observed in the fall until the 3d of November.

*Pressure.*—The mean reading of the barometer for 1880 was 30.092 inches, which is .039 of an inch above the average for nine years, and the highest annual mean recorded during that period. In each of the months, with the exception of September and December, the mean monthly pressure was higher than the average, varying from an excess of .004 of an inch in July, to as much as .153 of an inch in November. The highest means are found, as a rule, in the winter months, and the lowest in the summer; but there was an exception this year as regards December, for notwithstanding the unusually low temperature of the month its mean barometric pressure was but 30.048 inches, exceeding only the respective means of April, June, and July.

The range of the barometer was through 1.612 inches, from 29.163 inches, the lowest point reached in February, to 30.775 inches, the highest recorded in

<sup>1</sup> From advance sheets. Read December 7, 1881.

November. The former month was distinguished by the greatest barometric range, 1.474 inches, and July by the least, .854 of an inch. In general, the cold months were less equable as regards pressure than the warm ones.

**Rainfall.**—Only 33.58 inches of rain were recorded in 1880, or 8.36 inches less than the average precipitation during nine years; this is the least annual rainfall recorded in the Table which covers that period. The whole number of days on which rain or snow fell was 122, the average for eight years being 133. The lack in precipitation was divided, in unequal portions, among all the months save three, March, July, and December; the latter exceeded their averages, March very slightly, December 1.37 inches, and July as much as 2.52 inches, its rainfall of 7.74 inches being the highest recorded for any of the months. The least precipitation belonged to the exceptionally hot May, only .54 of an inch; from this value the months advanced as follows: September 1.10 inches, January 1.51 inches, June 1.67 inches, October 1.74 inches, November 1.75 inches, February and April each 2.43 inches, March 3.43 inches, December 4.05 inches, August 5.09 inches, and July, as noted above, 7.74 inches. The usual sequence of the months in this respect, and the average rainfall of each are as follows: May, September, and February each 2.52 inches, December 2.68 inches, January 2.93 inches, October 2.94 inches, March 3.31 inches, June 3.32 inches, September 3.39 inches, April 3.63 inches, November 3.78 inches, July 5.22 inches, and August 5.45 inches. Comparing the two sequences it will be seen that February, March, September, and December are the farthest removed from their accustomed positions, changes due chiefly to a diminished rainfall in the autumn, and an increased precipitation in December; the last month, indeed, was visited by several heavy snowstorms, one being especially severe. It will be observed, further, if the months be combined into their respective seasons, that the spring, like the fall, was comparatively dry, while the summer was about as wet as usual.

**Humidity.**—The mean annual humidity for 1880 is expressed as 66.8°, saturation = 100°; this is a little less than the average for seven years, 67.2°. The month of highest mean humidity was January, its 75° being as much as 2.2° beyond its average, and that of lowest, April, with a mean humidity of 57.1°, or 2.5° below its average. Between these two the months came in the following order: December with a mean humidity of 74.3°, August of 70.2°, February of 68.4°, November of 67.9°, October of 67.5°, March of 67.3°, September of 67°, July of 65.2°, June of 62.6°, May of 59°. The greatest deviations from the accustomed values, besides those of January and April just mentioned, were found in June, September, and December, the first two months falling below their averages in degrees of humidity respectively 2.8° and 2.7°, and the latter going 1.9° beyond its mean.

**Winds.**—As usual in other years the prevailing direction of the wind was, in 1880, southwesterly. In September, November, and December, however, the wind blew chiefly from the northwest, and in February from that quarter and due west equally. In June the winds were, for the most part, from due west, while during January and March northeast winds preponderated. In the latter month the wind blew with high velocity; in April there was a strong gale on the 30th day of the month.

**Electricity.**—Lightning was observed March 27th, and heavy thunder-storms were noted on the 4th and 7th days of April; also during May and July. In June, lightning was frequent; in August there were two auroras, on the 12th and 13th respectively, coinciding with hot and oppressive weather.

#### EPIDEMICS.

The number of deaths returned by the Registration Office of the Board of Health of Philadelphia for the year 1880<sup>1</sup> was larger than that for any year since 1876. The whole number was 17,711, exclusive of the still-born (870), and those deaths recorded as from "premature births" (231). The mortality is greater by 2240 deaths than that of the previous year, and gives an annual death-rate for Philadelphia, with its population of 846,980 souls (U. S. census), of 20.91 deaths to each thousand of inhabitants living, or 2.26 deaths per thousand inhabitants more than in 1879; the latter year, however, as I showed in my last report,<sup>2</sup> was the healthiest to be found in the records of the Health Office since the registration of deaths had been efficiently carried out in this city. The rate of 1880, comparatively high though it may be, is still below the average death-rate for the previous ten years (1870-1879), which I have calculated on the basis of the United States census of 1870 and that for 1880, assuming the increase of the population during the decade to have been in equal increments for each succeeding year, to be 21.65 deaths to each thousand inhabitants living. The mortality is, also, as it is wont to be, below, and in some instances, much below, that in the several American and foreign cities for 1880, the death-rates of which are as follows: New York 26.31 deaths per thousand inhabitants, Brooklyn 23.33, Boston 23.7, Baltimore 24.32, London 22.2, Paris 23.0, Berlin 23.9, Vienna 27.2, Amsterdam 27.2, Copenhagen 25.0, Stockholm 28.8, St. Petersburg 46.1, Madrid 40.1, Rome 32.0.<sup>3</sup>

In my report for 1879 I said that the low mortality of that year might have been anticipated from its meteorological conditions; in 1880, however, the climatic elements did not give a like favorable augury. The mildness of the early months, it is true, promised fewer deaths from diseases of the respiratory organs, but the early advent of hot weather in May, and its continuance into September, by adding to the length of the summer, the most unhealthy season of our year, gave grounds for apprehension that such reduction would be more than counterbalanced by the summer mortality, while the excessive cold of December foretold for that month more deaths from those causes which are most destructive in winter.

Of the 17,711 deaths reported, 9075 were of males, and the lesser number, 8636, of females. They were divided among the several ages as follows: under one year of age 4003, or 22.6 per cent. of the total mortality; between one and two years 1285, or 7.26 per cent.; between two and five years 1306, or 7.37 per cent.; between five and ten years 671, or 3.79 per cent.; between ten and fifteen years 322, or 1.82 per cent.; between fifteen and twenty years 503, or 2.84 per cent.; between twenty and thirty years 1834, or

<sup>1</sup> Fifty-three weeks have been counted in 1880; from the week ending January 3, 1880, to that ending January 1, 1881, inclusive.

<sup>2</sup> *Trans. Coll. Phys. Phila.*, 3d Series, vol. v.

<sup>3</sup> The death-rates of the foreign cities are taken from the annual summary of births, deaths, and causes of death in London, etc., 1880. London, 1881.

10.36 per cent.; between thirty and forty years 1657, or 9.36 per cent.; between forty and fifty years 1474, or 8.32 per cent.; between fifty and sixty years 1356, or 7.66 per cent.; between sixty and seventy years 1360, or 7.67 per cent.; between seventy and eighty years 1174, or 6.65 per cent.; and beyond eighty years 766, or 4.32 per cent. The percentages above mark, as usual, a greater mortality in the first years of life; as many as 37.23 per cent. of the whole number of deaths occurring in children under five years of age. In the previous exceptionally healthy year the proportion was 36.99 per cent., a percentage not very much less, so that the greater mortality of 1880 did not fall exclusively upon the very young.

In the classification of the deaths according to their causes (Table C), 3,810 of the whole number 17,711, or 21.51 per cent., are found in the class of Zymotic Diseases; 4,226, or 23.86 per cent., in that of Constitutional Diseases; 7,191, or 40.60 per cent., in that of Local Diseases; 1,794, or 10.13 per cent., in that of Developmental Diseases; and 673, or 3.80 per cent., in that of Violent Deaths; while 17, or one tenth of 1 per cent., are under the caption Causes not Specified, which last is made to include those cases in which the causes of death were too ill-defined to admit of proper classification. The percentage of the total mortality belonging to deaths from zymotic diseases in the previous year was 18.53, or about 2 per cent. of the mortality of 1880 less than in the latter year; on the other hand, while constitutional diseases caused 24.85 per cent., of the whole number of deaths in 1879, this class of maladies were in 1880 responsible for 1 per cent. less of the total mortality, though, on account of the large increase in the number of deaths from all causes in 1880, their actual mortality exceeded that from the same diseases in 1879; the proportion of deaths in 1879 from local diseases, 41.51 per cent., and that from developmental diseases, 11.58 per cent., are in each instance greater than fell to these classes in 1880, though, as with constitutional diseases, the real number of deaths from these diseases was larger in 1880 than in 1879; the percentage of mortality due to violent deaths in the earlier year, 3.46 per cent., was somewhat less than that calculated for the same class in 1880.

When we compare the actual number of deaths from zymotic diseases in the two years we find the excess in 1880 to be 943, or about one third of the mortality in 1879. This increase was due especially to the prevalence of small-pox; measles also caused some deaths, and the mortality from typhoid fever was markedly aggravated; there were also more deaths from cholera infantum; on the other hand, scarlatina diminished the number of its victims, while diphtheria, croup, and whooping-cough each claimed for itself about the same number of deaths in the two years.

The reappearance of *small-pox* among the causes of death at the close of the year 1879, was followed by a mortality of 421 in 1880. The whole number of cases of the disease reported to the Health Office during the year being 1832<sup>1</sup> it would follow that the mortality was one death in 4.32 cases. There were, however, undoubtedly many light cases of variolous disease which failed to reach the Health Office, and even some severe ones, since it is not very difficult to hide a case when death does not occur, so that it is

probable that the disease was not so fatal as it appears. According to the returns, the ratio of the deaths to cases varied very much in the several wards, for while there were twelve cases reported in the Ninth Ward with no deaths, eleven in the Thirteenth, also without a death, and seventeen cases with but one death in the Thirtieth, there was in the Seventeenth and Twenty-eighth Wards one death to about every four cases reported.

With the exception of the Ninth and Thirteenth Wards, already mentioned, there were deaths from small-pox in each of the wards of the city (Table E); but the Twelfth, Twenty-seventh, and Thirtieth had each only one death from the disease, and the Eighth, Eleventh, and Twenty-first each only two. The most deaths were reported from the Twenty-eighth Ward, 119; but these included the deaths in the Municipal Hospital for Contagious Diseases, to which cases of small-pox from all parts of the city were taken; excluding these, 79 in number, the deaths really belonging to the ward are, however, as many as 40. In the Second Ward 46 persons died from the disease, in the Fourth 34, in the Thirty-first 31, in the Nineteenth 27, in the First 21, in the Twenty-fifth 20, the Third 14, and the Seventh 11. Each of the remaining wards had 10 or a less number of deaths. If we group the wards together we will find that in the southern section of the city — all that part below South Street, and east of Broad Street, comprising the First, Second, Third, and Fourth Wards — there were, in a population of 108,707 souls, deaths from small-pox to the number of 115, or a death-rate from the disease of 10.5 to the 10,000 inhabitants; all these deaths took place in and after the month of August. In another group of wards in the northeastern quarter of the city, comprising the ward in which small-pox first appeared in the previous year, namely, the Twenty-fifth, the Nineteenth, the Thirty-first, and the Twenty-eighth, excluding the deaths at the Small-pox Hospital, there were 118 deaths among a population of 145,741, or a death-rate of 8.10 per each 10,000; in this district the deaths were distributed throughout the whole year, though the summer was nearly exempt. These two groups of wards are the same in which the small-pox raged most fiercely in the great epidemic of 1871-72, and again in the lesser one of 1876. Between these two districts stretches the part of the city where the population becomes densest, the greatest movement of business is to be found, and the wealthier classes have their homes (the Fifth, Sixth, Seventh, Eighth, Ninth, Tenth, Eleventh, Twelfth, Thirteenth, Fourteenth, Fifteenth, Sixteenth, Seventeenth, Eighteenth, Twentieth, and Twenty-ninth Wards); here, in a population of 380,934, there were but 85 deaths, or 2.2 to each 10,000 of inhabitants.

It may seem at first sight singular that the disease passed comparatively harmlessly over the latter region to establish itself in the southern wards with more virulence than it displayed in its birthplace, but no doubt the explanation is to be found in the greater attention paid to vaccination and cleanliness in the richer quarter of the town. In the outer circle of wards, Twenty-first (Manayunk), Twenty-second (Germantown), Twenty-third (Frankford and Bridesburg), Twenty-fourth and Twenty-seventh (West Philadelphia), Twenty-sixth and Thirtieth, the aggregate population of which is 165,206 souls, there were but 27 deaths, or 1.6 to each 10,000 of inhabitants.

<sup>1</sup> Health Office's Annual Report, etc., 1880, page 172. Philadelphia, 1881.

The distance of these districts from the focus of the disease suggests itself as the cause of their comparative exemption.

Of the deaths from small-pox, 36 were recorded for the first quarter of the year, 21 for the second, 50 for the third, and as many as 317 for the last quarter; the figures show the insidious advance of the disease, not many deaths during the first three months, then a decline in the number in the second quarter, during which the lowest monthly mortality, four, was reached; in the third quarter a rise to a number of deaths almost equal to that recorded for the whole first half of the year, and finally in the last quarter a mortality nearly three times as great as that returned for all the preceding quarters of the year, the closing month, December, claiming the maximum monthly mortality, 189. A tendency in small-pox to a diminished mortality or disappearance in the summer, and to a beginning or increase in the number of cases in the later months of the year has been shown in Philadelphia during and since the severe epidemic of 1871-1872; before that event registration was not full enough to have data to elucidate these points. In the epidemic mentioned the deaths from the disease began to increase in the early autumn; there was a marked rise in the mortality during the first week in October, after which the progress of the disease was very rapid; the winter gave a high mortality, but by the time the summer came the scourge had nearly disappeared, and there was no rekindling of the dying flame in that fall or the succeeding winter, the disease entirely vanishing from the causes of death in the following summer. Subsequently there was very little small-pox in Philadelphia till the fall of 1875, when a sharp increase in the number of its deaths took place, followed by a small epidemic in 1876, which diminished, however, in mortality in the summer, to increase a little in the fall of that year, and finally to disappear entirely in the summer of 1877; after which the mortuary lists were free from small-pox until the reappearance of the disease in the fall of 1879. Briefly to recapitulate, we have the great epidemic of 1871-1872, beginning in the fall of 1871, the much smaller one of 1876 beginning in the autumn of 1875, again a new appearance of the disease in the last months of 1879, and a large increase in its mortality during the autumn of 1880, after the deaths had diminished to a very few during the summer of that year. The Registrar-General of England, in his "Annual Summary"<sup>1</sup> for 1880, calls attention to a like seasonal distribution of the deaths from small-pox in London, the observations extending over five years; but such distribution has not been generally noted in other places. It is perhaps to be accounted for in the same way that we explain the greater prevalence of typhus in winter, by the greater deficiency of ventilation in houses, and the keeping within doors at that season; conditions favorable to the accumulation and reception of the poison of the disease.

Speaking in my report for 1879 of small-pox, I detailed the measures of isolation, vaccination, revaccination, and purification of surroundings instituted by the health authorities of the city to oppose the march of the disease, and there can be no doubt that these were effective in staying its ravages; but these authorities were armed with no law to compel obedience to their mandates, and in a few months even the money

appropriated to carry them out was exhausted. Then their hands were to a certain extent tied — not entirely, for vaccination and the removal of nuisances still went on, but only by the good-will of the vaccine physicians, and as regards the purification of places by more indirect methods of the health officer. Finally, after vexatious delays, more money was secured for vaccination, and the work went on more briskly. It would take, indeed, what seems to legislators an immense amount of money for such a purpose to stamp out small-pox in so large a city as Philadelphia. According to Curschman<sup>2</sup> the duration of immunity from the disease under exposure after vaccination may be stated at from eight to ten or twelve years. If we put it at ten years there would then be required in our population of, in round numbers, 850,000 inhabitants, a yearly average of 85,000 vaccinations and revaccinations to keep the city protected; that is, one tenth of the whole population would need to have the operation performed upon it each year. This would cost the city, if it were responsible for the whole expense of vaccination, at the rate now paid in Philadelphia for public vaccination, about \$10,000 yearly — really a very insignificant sum when the enormous benefit to be derived is considered, but immense, as I have said, in the estimation of our legislators. Of course, in reality, a very large number of persons are vaccinated or revaccinated at their own expense; how many there is no means of accurately estimating, but I should think that the city ought to be prepared to vaccinate or revaccinate at least 10,000 persons yearly, for although nothing like that proportion of persons accept gratuitous medical relief, a very large number who are willing to pay a physician when they are sick will not incur the expense of vaccination to prevent a sickness which they hope may never come upon them. In fact, there were performed in Philadelphia during the ten years preceding 1880, in round numbers, 130,000 successful operations;<sup>3</sup> while, if my estimates are plausible, there should have been about 400,000, or as many as 270,000 more. Adding to the last number the average yearly estimate of 85,000 to be vaccinated, Philadelphia found herself at the beginning of 1880 with about 350,000 persons to vaccinate, in order to be thoroughly protected from small-pox. These figures are not presumed to be more than approximately correct, yet they are, perhaps, close enough to the truth to show what a wide field in the direction of vaccination lay before the Health Board when confronted by the epidemic. The number of operations really paid for by the Board in 1880 (and for such only is compensation given) was but 28,415, so that it was hardly to be expected that the end of the year would witness the abolition of the epidemic. The unprotected persons were, however, scattered throughout the whole community, and this absence of aggregation is perhaps the reason why the devastation from the disease was not greater. Those persons especially received the care of the vaccine physician who, from contiguity to the sick, were most likely to be attacked by variola. Incomplete as I have shown were the means adopted to eradicate the disease, yet, in a letter which I wrote as correspondent to the Bulletin of the National Board of Health, I claimed a certain measure of success for them in instancing in

<sup>2</sup> Encyclopedia of the Practice of Medicine, Ziemssen, vol. ii., p. 406, Am. Edition, New York, William Wood & Co., 1875.

<sup>3</sup> Records of Health Office.

<sup>1</sup> Ibid., pp. x., xi.

comparison the course of the disease in the neighboring city of Camden, where even so much was not done. Small-pox was imported into Camden from Philadelphia in February, 1880, and caused there, as I was informed by Dr. James Wroth, of that city, in the course of one year 131 deaths among a population of 41,638 inhabitants; the same proportion of deaths in Philadelphia would have given 2665 for that city instead of the 424 deaths recorded. The fact, however, is not to be lost sight of that epidemics are always liable to be more severe in small than large cities, probably from other causes than the want of sanitary protection.

The comparatively large number of deaths from measles, 108, the largest in any year since 1874, represents a great multitude of cases of the disease, since the affection is so rarely fatal, even with its complications. It is so contagious a malady that when it appears in a community it runs among the children like wildfire; given its occurrence in a family of the poorer classes, who use much in common, it will not only attack, with very rare exceptions, all the children under the same roof, but spread to the next house, and so on, till in a very short time it has searched out every child in the neighborhood not protected by a previous attack of the disease.

Deaths from measles were reported from each one of the city wards but four (the Sixth, Ninth, Twenty-first, and Twenty-seventh), so that the zymotic was very widely diffused, as follows naturally from its very contagious nature. The aggregate of deaths caused by it were, however, comparatively so few, that when divided among the twenty-seven invaded wards, the numbers for each are too insignificant to admit of profitable comparison of the respective mortality of these small divisions of the municipality. If, however, groups of wards be taken together as single districts, those, for instance, defined above in discussing the distribution of the deaths from small-pox, it will be seen that the better-placed "old city proper" had no fewer deaths than those other parts of the city which were the principal sufferers as regards small-pox. The mortality from measles was five in January, 20 in February, 38 in March, 29 in April, nine in May, and four in June, when the epidemic may be said to have come to an end, though there were three deaths subsequently, namely, one in October and two in December. It will be noted that the deaths had a small beginning in January, growing more numerous quite rapidly till the maximum was reached in March, the month distinguished beyond all others in this climate for fatal affections of the air passages, and that they reached zero in the summer, the season when the same diseases have their lowest death-rate. Evidently those were the complications which heightened the mortality in this otherwise trivial disease.

There were fewer deaths from *scarlatina* in 1880 than in any year since 1872; indeed, including the latter year, there have been only four years since 1861 (at which time our records begin to be reliable) in which a lower death-rate from this fever was observed. Nevertheless, in the rural wards, to the north of the central city, the Twenty-first (Mammyunk), Twenty-second (Germantown), and twenty-third (Frankford and Bridesburg), the mortality from the disease was greater than during the previous year; in the last ward the deaths increased from six in 1869 to as many as 26, the latter giving a rate of about 10

deaths to every 10,000 inhabitants living. Tracing briefly in my report for 1879 the cause of *scarlatina* in previous years, I forecast this diminution of mortality in 1880, but also deemed an increase in the number of the deaths from *scarlatina* probable at the close of that year.<sup>1</sup> We shall see by referring to the monthly mortality that the latter actually took place (Table E): January 17 deaths, February 28, March 11, April 17, May 32, June 39, July 11, August 20, September 17, October 16, November 32, and December 50.

We find that *diphtheria* caused 323 deaths in 1880, just two more than the number reported for 1879; its distribution through the city was not much different from that noted in the latter year, though the outlying Twenty-second and Twenty-third Wards each counted more deaths from the zymotic; in the former (Germantown) there were 33 deaths where there had been 17 in the previous year, giving a death-rate of about 10 to the 10,000 inhabitants in 1880, and in the latter ward 20 deaths instead of 10, or a death-rate increased to 7.5 to the 10,000 inhabitants; but these figures are considerably above those which express the mortality from *diphtheria* throughout the whole city, which I have calculated to be 3.4 deaths to the unit of 10,000 inhabitants. The seasonal distribution of the disease was the usual one, more deaths in the cold, less in the warm, weather; 97 deaths in the first quarter of the year, 72 in the second, 41 in the third, and 101 in the last quarter. The approach to equality in the number of deaths in the years 1880 and 1879 is characteristic of the rather sluggish course of *diphtheria* in Philadelphia, as it changes for better or for worse; this much-dreaded disease has never taken the severe hold upon this community to which the records of some other cities bear witness.

As with *diphtheria*, the 503 deaths from *croup*, set down for 1880, approximate quite closely in number to the 291 from the same cause in the previous year. These deaths were scattered over the whole city, but the wards forming a group in the northeastern section of the city (Sixteenth, Seventeenth, Eighteenth, Nineteenth, Twentieth, and Thirty-first) and two wards in the southern part of the city (Second and Twenty-sixth) were the greatest sufferers, the mortality in these districts being from 5 to 8 to each 10,000 inhabitants, while in the remaining wards of the city the death-rate did not exceed from 1 to 4 deaths in an equal number of people. Of the rural wards, the Twenty-second (Germantown) and Twenty-third (Frankford and Bridesburg) had only from 1 to 2 deaths in each 10,000 inhabitants, but the Twenty-first (Mammyunk) had as many as 4 deaths in that number. There is nothing unusual in this distribution of the disease; the central sections of the city are wont to be less severely attacked by *croup* and some other of the zymotic diseases than the northeastern and southern districts, while the outlying wards vary as regards its prevalence, being sometimes classed with the more unfortunate districts, and again being in company with the less afflicted central wards of the city.

The deaths from *croup* were divided among the quarters of the year in a proportion strikingly similar to that recorded for *diphtheria*, there being in the first quarter 107 deaths, in the second 62, in the third 42,

<sup>1</sup> Report of Meteorology and Epidemics for 1879. Transactions Coll. Phys. Phila., 3d Series, vol. v., pp. 92-93.

and in the fourth quarter 91. The two diseases are so similar, if they be not identical, that the same case would be returned by one physician as diphtheria, and by another as croup; so that if they are really different diseases, their true relative proportion is hopelessly confused in the records.

The mortality from *typhoid fever*, which had been decreasing annually since 1876, in which year it will be remembered the deaths were double the yearly average, now in 1880 advanced to 125, an increase over the mortality of the previous year of 151 deaths, or forty-four per cent. The death-rate, 5.8 deaths to each 10,000 inhabitants living, is, however, but very little more than the average mortality from typhoid fever during the ten years preceding 1876.<sup>1</sup> This increase in the mortality from typhoid fever in 1880 extended over nearly the whole city, since there were only five wards, the Eighth, Ninth, Tenth, Twelfth, and Twenty-sixth, in which there were fewer deaths from the fever than in the preceding year; and only two, the Eleventh and Twenty-third, in which the mortality was the same in the two years. The central wards, comprising the old "city proper" (Fifth, Sixth, Seventh, Eighth, Ninth, Tenth Wards), were, generally speaking, the least severely visited by the disease; here, in a population of 112,848 souls, there were 41 deaths, or a ratio of 3.9 to the 10,000 inhabitants, while in the territory to the northeast (Eleventh, Twelfth, Thirteenth, Fourteenth, Sixteenth, Seventeenth, Eighteenth, Nineteenth, Thirty-first and Twenty-fifth Wards), including the old districts of Kensington and Richmond, there were, in a population of 290,733, as many as 202 deaths, or a ratio of 6.9. In the southern section of the city (First, Second, Third, Fourth, Twenty-sixth and Thirtieth Wards) the ratio was but a little less favorable than the latter, being 5.9 deaths to each 10,000 inhabitants among 172,945 people. West Philadelphia (Twenty-fourth and Twenty-seventh Wards) was nearly as bad as this, having a ratio of 5.2 deaths to the 10,000 with its 69,341 inhabitants. The Fifteenth, Twenty-ninth, and Twenty-eighth Wards in the northwest had death-rates from the fever respectively of 4.8, 6.1, and 3.1 to the same unit, while the outlying rural wards, Twenty-first (Manayunk), and Twenty-second (Germantown), had each rates of 6.6, and the Twenty-third (Frankford and Bridesburg) 6; the last ward has had this comparatively large share of mortality from typhoid fever for several years past.

The apportionment of the deaths from typhoid fever throughout the year followed the distribution which I have so often pointed out for them. The mortality in the several months was as follows: January 39, February 29, March 35, April 27, May 31, June 24, July 40, August 65, September 46, October 38, November 29, December 72. A maximum occurred in August, and another in December, the latter appearing to have the most value, as happened really the previous year. I say appearing, because if we consult Table D we will see that the month of December has been made to embrace five weeks, while that of August contains but four, so that the excess in the former month is not a real one. I have repeated a diagram, which I drew for my report for 1876, containing a curve representing the monthly variations in the number of deaths from typhoid fever in that year, with another

depicting the average monthly variations for the previous ten years, and I have added to them a third line to show the mortality from the fever in the several months of 1880. A truly remarkable similarity appears between all the curves, bearing witness to the

*Curves Representing the Monthly Mortality of Typhoid Fever during 1876 and 1880, and the Average Monthly Mortality of the same for Ten Years 1869-1878.*

A. Mortality curve for 1876. B. Curve for 1880. C. Curve of averages.

constancy of "the periodical distribution" of the zymotic, and suggesting that this should always be taken into consideration when estimating the efficacy of any particular measures which may have seemed in some special instances to have successfully prevailed against the disease. The mild winter and the early and prolonged summer doubtless played an important part in bringing about the increase in the number of deaths from typhoid fever during the latter half of the year, as I attempted to show in my report for 1876 was the case under similar climatic conditions in that year.

There were reported a few deaths from *typhus fever* in Philadelphia in 1880, according to the death-list, 23; and that some of these, at least, followed true typhus is vouched for by physicians well qualified to decide. The deaths were scattered, however, through several months (Table D), and were not numerous enough to excite apprehension of a serious epidemic.

The preponderance in the number of deaths from constitutional diseases in 1880, already alluded to, is in most part due to a greater mortality from tubercular diseases, and especially from *phthisis pulmonalis*. The deaths from *tabes mesenterica* bear a marked relation to climatic heat, but the connection of consumption with temperature is not so apparent; if in Table D the fact be kept in view that some of the months are made to include five weeks, while the others contain only four, the mortality from the latter disease will be found to have been divided not very unevenly through the year. Yet a certain connection will be observed between cold and an increased death-rate among the several months, but then there will appear a paradox in the fact, that in a year so exceptionally genial as we have seen 1880 to have been, the mortality from consumption exceeded that of the previous and some other years (Table C). The explanation, of course, is that there are other factors in determin-

<sup>1</sup> Rep. on Met. and Epidem., Trans. Coll. Phys. Phila., 3d Series, vol. iv., page 63.

ing this rate more potent than degrees of temperature; a truism, by the way, which should lead us to the practical inference that too much is not to be expected from a change of climate as regards the effects of the climate, *per se*, towards the cure of a case of consumption. Experience shows that though from year to year we may have such a variation in the mortality from phthisis as has occurred between 1880 and the previous year, yet there are not those wide differences that are found in the death-rates of zymotic diseases. Hence, even if it should be proved true that fell consumption is allied to these in having for its cause some microscopic germ, it would seem that this poison is more constant in its degrees of virulence than those which occasion periodical epidemics of other diseases. We might reasonably explain the difference in the annual death-rates, since excesses of climate fail us, by changes in the modes of life — business pursuits, mental strain. It would appear then not unlikely that the revival of business, which began in the autumn of 1879, by creating new anxieties and giving incentive to overwork, was responsible for some additional deaths from phthisis pulmonalis.

The difference in the mortality from local diseases, the 7191 deaths in this class exceeding the number in the previous year by 769, seems to have been due in great measure to the disturbing influence of the early accession of summer heat. It belongs chiefly to the diseases of the nervous system, and, among these, especially to *cephalitis* and *convulsions*, terms often used by those who write death-certificates to express the causes of death in infants during the hot weather. The mortality from *sunstroke*, in the same class, is seen to be increased from three in the previous year to 37 in 1880, and of these as many as 23 to have occurred before the month of July (Table D), a very exceptionally early period for the climax of this disorder.

I presume, as with phthisis, the renewed activity in business will account for the larger number of deaths in 1880 classed under violent deaths: the risk of accidents is greater in the turmoil of busy life.

[The Tables referred to will be found in the Report.]

#### FOUR CASES OF NERVE STRETCHING FOR AFFECTIONS OF THE SPINAL CORD IN THE CLINIC OF PROFESSOR TIERSCH, LEIPZIG. NO BENEFICIAL RESULT.

REPORTED BY GEORGE L. WALTON, M. D.

THESE cases occurred in the clinic of Professor Tiersch in the St. Jacobs Hospital, at Leipzig, and will be interesting to add to the statistics of this operation.

In three of the cases the operation was performed at the earnest desire of the patients.

In no one of the four was the slightest permanent improvement discovered, though in three a slight transient improvement appeared in certain symptoms.

CASE I. R., a varnisher, thirty-five years old, has spastic spinal paralysis, the symptoms of which began about six years ago after an attack of typhoid fever. Since that time has complained of numbness, weakness, and dragging in the legs, together with girdling pains around the abdomen.

*Status before the operation.* Patient is a middle-sized, well-nourished man. Internal organs normal. From the first to the twelfth dorsal vertebra is a sco-

liosis with its convexity to the right; below, a compensating scoliosis with its convexity to the left.

No kyphosis. Vertebrae nowhere tender to pressure.

The upper extremities are normal, and without exaggerated reflexes. Lower extremities not atrophied, but movements are weak, especially in the left. Patient can, however, move both limbs slowly. Quick movements are impossible on account of contractions. No ataxia. Sensibility not affected. Tendon reflexes in left leg considerably, and in right slightly exaggerated.

*Foot phenomenon present.* The gait is purely spastic.

Both sciatic nerves were stretched as follows: Patient was chloroformed and laid on the belly. The region of the incision was shaved and carbolyzed. An incision was made ten centimetres in length from the lower edge of the gluteus maximus downwards. The nerve was laid free, taken out with the finger and stretched centrally and peripherally. The stretching was done so forcibly that the patient was lifted by the buttocks from the table. A drainage tube was inserted and the wound sewed with silk. Carbolyzed bandage.

After the operation the foot phenomenon had disappeared on both sides, and the patella reflex was much lessened. Patient could move the feet well.

First day after the operation. Patient complained of burning in the wound and pricking in the heels.

Second day. Pain has disappeared, also the reflexes in lower extremities. On attempting to walk the patient does not drag the legs as before, but raises the feet and sets them down on the whole sole. He says he moves with greater ease than before the operation.

Third day. The stitches somewhat reddened. Drainage tubes and half the stitches removed.

Fifth day. The remaining stitches removed as well as the antiseptic dressing. Plaster applied. The gait has now resumed its former character.

Sixth day. Wound on the right leg somewhat spread. Plaster. Complaints of dragging pains in limbs.

Thirteenth day. Patella reflex again present; in the left leg, stronger than normal. Dragging pains continue in the left leg, and he complains of painful spots.

Fourteenth day. Both wounds entirely healed. Patient is out of bed and goes about.

According to the opinion of the attending surgeons as well as that of the medical side the condition of the patient is exactly the same as before the operation.

CASE II. E. H., twenty-eight years old, postmaster. Disease of the lumbar region of the cord. Patient says he has been generally well and has had no venereal disease. At the age of nineteen had cutaneous ulcers which came spontaneously.

For about four years he has had "rheumatic" pains, very severe at night, seemingly felt in the bones of the leg.

The pains have not affected his gait, and until four weeks ago he could walk well in the dark and with closed eyes. He is married and has two children, one four, and the other one year old.

One year ago he had an inflammation of the left testicle which ended in atrophy.

About four weeks ago he began to notice a difficulty in getting about, and at this time was obliged to use a cane, which had not previously been necessary.

At the end of a week he could no longer use his

legs, and at the same time lost control over urine and feces. The bladder had to be emptied by the catheter. Two weeks later there was a slight improvement; the bladder and rectum were again under control of the patient, and the urine previously cloudy became clearer. In the last few days he has been able to move his toes a little.

Status before the operation. Head and trunk normal. Axillary and cubital glands somewhat swelled.

Lower extremities. On the skin of the shin are several flat, partially pigmented, not retracted, silver white scars. Edge of tibia is somewhat rough. Right lower extremity completely paralyzed. Of the left, can move the toes. Sensibility decidedly lessened, especially on plantar surface of toes. Complete absence of tendon and skin reflexes.

Urine passed spontaneously, slightly cloudy. Slight constipation. Patient remained in the hospital eighteen days, during which there was a slight improvement in motion, followed by a return to the former state of paralysis, with an increase in the reflexes.

The pupils were at this time unaffected by light, but contracted with the effort of accommodation.

The sciatic nerves were now stretched at the wish of the patient. The details of the operation were the same as in the previous case.

First day after operation general condition bad, micturition difficult. Bandage changed on the third day, and the stitches removed. On the sixth day the antiseptic dressing was discontinued. Eleventh day, complete motor paralysis of lower extremities; sensibility somewhat improved, that to pain has returned; skin reflexes in slight degree present; tendon reflex fails entirely; sphincter ani paretic; catarrh of bladder better, some dripping of urine. Twenty-second day after the operation, wounds healed excepting the points of drainage; condition of the patient not in the least improved by the operation.

CASE III. F. R., coachman, forty-nine years old, *tabes dorsalis*. No history of syphilis; no genital discharges.

Twenty years ago began to suffer from lancinating pains in the lower extremities. For thirteen years had no further symptoms. During the past seven years the pains have been more severe, and patient has noticed a weakness in the legs, and an irregularity in his gait, especially in the dark. Sphincters have been paralyzed; has had girdle pains around the abdomen, and frequent pollutions. The last coitus, seven years ago, was normal. Within the past three years the sphincter paralysis has disappeared. The lancinating pains have attacked the region of the sacrum, both arms, and face. The pupils are alike, of middle size, and contract on accommodation, but not to light; ataxic movements in arms; sensibility to touch and pain normal; in lower extremities pressure sense lost, pain sense present, but delayed; temperature sense lessened; sense of position good; patella reflex wanting on both sides; marked ataxic movements of lower extremities; no incontinence, but patient has to press hard in micturating.

At the request of the patient the sciatic nerves were stretched. The left wound was treated with powdered iodoform, and sewed without drainage. The right was treated with antiseptic precautions and a fine drainage tube was inserted.

This patient had considerable fever after the operation, and pain in the wounds, which healed slowly,

especially the left one. This at the end of six weeks presented a large, deep cavity with flabby, shining granulations. At this time the wound on the right side was nearly healed.

The sensibility seems to have improved slightly after the operation as well as the tabetic symptoms, which were, however, at the end of four months at their former standpoint. The tendon reflex was possibly temporarily improved, but if so it disappeared again.

During the patient's stay in the hospital the lancinating and constricting pains recurred at intervals.

CASE IV. This was a typical case of *tabes dorsalis*, not very advanced, in a man of middle age. The disease was probably of syphilitic origin. The principal symptoms were girdling and lancinating pains, slight ataxia, diminished pressure and muscle sense. Tendon reflexes failed; the pupils reacted sluggishly to light; no paralysis of bladder or rectum. The lancinating pains, which were of unusual severity, constituted the most troublesome symptom.

Various methods of treatment, including a thorough course of mercurial innunction, having been tried without result, the patient requested that the nerves should be stretched. The operation was performed under Lister. The wounds healed very slowly, and the patient was much reduced.

For a short time after the operation there seemed to be a slight return of sensation in the feet, and through this an improvement in the ataxia. The improvement was, however, temporary, and when the patient was discharged his condition was in no respect better than when he entered the hospital.

It is particularly worthy of note that the pains in this, as well as in the other case of *tabes*, were not in the slightest degree lessened in frequency or intensity by the operation.

## Hospital Practice and Clinical Memoranda.

A CASE OF RETAINED PLACENTA; PROTRACTED CONVALESCENCE; REPEATED CHILLS AND FEVER ALTERNATING WITH DAYS OF COMFORT WITH NORMAL TEMPERATURE.<sup>1</sup>

BY W. W. WELLINGTON, M. D.

On April 13th I attended Mrs. II. in her first confinement; she was in labor eight hours; natural, with the exception that the placenta was retained by an irregular contraction of womb, making it necessary to pass the hand through the contracted portion in order to deliver it. It was necessary also to pass the hand into the womb twice in order to remove conglua and to secure contraction. After labor, the patient was comfortable, bright, took nourishment, and had no after pains.

April 14th, A. M. Slept well last night, and bright this morning. At noon had a severe chill, followed by heat and sweating, and accompanied by headache, pulse 130; temperature 105° F.; no abdominal tenderness or swelling; womb well contracted; a quart or more of urine drawn by catheter. At evening pulse 100; temperature 103° F.

April 15th, A. M. Pulse 120; temperature 102.5° F.

<sup>1</sup> Read before the Obstetrical Society of Boston, November 12, 1881.

Only complaint was of weariness, and a feeling as though she had been pounded. The night had been restless; she was thirsty; no abdominal pain, tenderness, or swelling; can move in bed easily; tongue moist; there was no albumen in the urine, and the quantity secreted was normal; drinks milk freely; not much flowing; lochia slightly offensive. In evening, pulse 106; temperature 104° F.

April 16th, A. M. Symptoms all relieved; pulse 96; temperature 101.5° F.; had a good night; less pain in head; no pain or soreness in abdomen; lochia slightly offensive. P. M. Another chill, not very severe; pulse 100; temperature 105° F. Abdomen a little tender and swollen; bad feeling in the head; breasts full, with a fair secretion of milk; two spontaneous dejections.

April 17th. Pulse 92; temperature 102.3°; had a good night; better every way; breasts full; a small spot of tenderness in the abdomen. (Its exact position is not stated in my notes.) Lochia less offensive.

April 18th. Very comfortable. 19th. Comfortable; pulse 88; temperature 99° F. 20th. Pulse 90; temperature 99° F.; frequent desire to urinate.

April 21st. (Ninth day.) Chill at midnight. In morning, pulse 120; temperature 105° F.; severe headache; heavy and somewhat stupid; no appetite; thirst; secretion of milk nearly arrested; no abdominal tenderness. In evening, temperature 103° F.; feeling better generally.

April 22d. Pulse 96; temperature 98.5° F.; bad symptoms have passed off; slight dysuria.

April 23d. At morning visit, all right; in evening fever, but no chill; pulse 112; temperature 104° F. worried in mind and unable to sleep; vaginal examination reveals nothing; os uteri closed; no tenderness about womb; lochia slight; no offensive odor.

April 24th. (Twelfth day.) At morning visit, pulse 100; temperature 103° F. feeling better, but had not slept well. In evening, pulse and temperature normal; sitting up in bed and eating her supper, consisting of bread and milk. Says she feels "first rate."

April 25th. Pulse and temperature normal; feels well.

April 27th. (Fifteenth day.) Last evening, had a fever turn of considerable severity without a chill; this was attended with headache, pain in back, and sleeplessness, and was followed by perspiration lasting all night. At one time both arms and hands were rigid for a few minutes, suggesting convulsions; breasts became soft, and milk thin and watery. This morning, pulse 104; temperature 101.5° F.; a tender spot in left iliac region; sleepy and stupid. P. M. Had slept well all day and was feeling better.

April 28th. Pulse 96; temperature 100.4° F. Feeling well; milk has returned; has slept well; can move in bed without pain; headache and abdominal tenderness have departed.

April 29th. Pulse 90; temperature 100.2° F.; comfortable.

April 30th. Pulse 90; temperature 99.8° F.; comfortable.

May 1st, A. M. Pulse 90; temperature 99.8° F.; with exception of pulse and temperature seems perfectly well.

April 26th. Pulse and temperature normal; feels well.

May 2d. Pulse 80; temperature 100° F. Yesterday, P. M., had a nervous hysterical turn, lasting a

couple of hours, during which the head was hot, and there was much mental worryment. To-day, professes to feel well and really seems so. Lochia slight and a little offensive.

May 3d. Pulse 96; temperature 100° F.; comfortable.

May 4th. Pulse 90; temperature 100° F. Slight fever turn yesterday P. M.; comfortable to-day.

May 6th. Pulse 96; temperature 100.4° F. A small clot passed from vagina, with some offensive discharge; reports herself as perfectly well. Sits up two hours at a time.

May 7th. (Twenty-fourth day.) Yesterday, after "sitting upon her feet" in bed (a peculiarity of hers) had a pain in right leg, which has continued. This evening leg is painful and swollen; cannot lift it up; tenderness in groin, along inside of thigh, and in calf of leg. No chill; pulse 100; temperature 102° F.; no pain; appetite fair.

The inflammation of the leg continued for a few days, and on the 16th of May (the thirty-third day after her confinement) I made my last visit. The lady has been well ever since.

The changes from grave to gay were in this case sudden, numerous, and irregular. The first chill occurred within twenty-four hours of the end of the labor. The febrile symptoms (temperature 105° F.) passed off in two days. Immediately another chill (temperature 105° F.) and the bad symptoms departing the next day. The third chill, four days after (temperature 105° F.), the fever subsiding the next day. On the day following, fever without chills (temperature 104° F.), subsiding the next day. Three days after, fever without chill (temperature 101.5° F.), subsiding the next day. Four days after, the nervous or hysterical turn; relieved the next day. Four days after, the phlebitis of the leg, continuing ten days. The uterus was after labor supposed to be thoroughly emptied, and during the whole time there was no abdominal inflammation of any considerable amount.

## Reports of Societies.

### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

At the meeting of November 12, 1881, DR. HALL CURTIS read a paper on Tumor Formations in Acute Pelvic Inflammation, which will be published hereafter.

### THE CHIN ON THE PUBES AFTER VERSION; CRANIOTOMY.

DR. FORSTER read the following case:—

The following is briefly reported as being of interest, as the operation performed is one which the general practitioner is seldom called upon to undertake.

Last Wednesday evening I was summoned to meet two of my professional friends and bring my cranioclast, or instruments for craniotomy. I answered the summons taking with me my Smellie's scissors, fork, etc.

I found a colored woman in bed in her second pregnancy, labor having begun twenty-four hours previously. The antero-posterior diameter was very much diminished. Efforts at delivery with forceps having failed version had been performed and the child delivered with the exception of the head, which

was left with the chin resting on the pubes. The child was dead when seen by me. All efforts to bring the occiput to the front having failed, I borrowed from Dr. R. his trephine and Braun's cranioclast, and the attendant with the former opened the cranium, and with the aid of the latter the woman was rapidly delivered. The delivery was accomplished at 10.15. The patient succumbed at 11.20 from shock and exhaustion.

The interest lies in the version, which, if properly performed, should have brought the occiput to the front.

Dr. RICHARDSON said that within the last three years he had four times performed craniotomy under similar circumstances, for men of repute in the profession, and that this was his reason for referring to a subject which has been generally supposed to be universally understood. It was necessary, he remarked, in performing version to bear in mind the whole of the operation. In the cases referred to the operators had not kept steadily in view the necessity of combining rotation with traction in order ultimately to bring the occiput to the front. The chin consequently became hooked over the pubes and the more firmly and decidedly the greater the traction then made. Under these circumstances Dr. Richardson said it was often impossible to disengage the chin, whether by rotation of the body or pushing up the head, or both combined, as the head would invariably return to its fixed position as soon as traction was again made, unless a completed rotation was effected. This latter it was very difficult to perform.

Dr. FORSTER stated that he had tried rotation, but the neck was so distended that torsion of the body could not be conveyed to the head.

Dr. Forster remarked that the lock of the cranioclast was so near the fenestrum of the blades that in this case when first applied they did not sufficiently grasp the skull but pulled away a portion. When applied properly the lock is entirely out of sight, and consequently there is the danger (as in this case) of having them in sight when locking as with forceps, thinking the relative distances are the same, and thus failing to obtain a proper hold on the head.

Dr. INGALLS observed that within a very few years several cases had been reported to the Society, of a position of the head after version similar to that described by Dr. Forster; one of these by Dr. Fifield, another by Dr. C. E. Stedman. In these instances, the woman having been placed on her side with the upper knee held far apart from the other, a towel was wrapped about the infant, whose back was then turned up along the back of the mother, making a plane of the child's abdominal walls, from chin to pubes, delivery safely following. Dr. Ingalls stated that he had himself safely delivered, within the past two years, two children, when after delivery of the lower extremities the remainder, excepting the head, had pushed into the world with unusual rapidity, and so had failed to get the necessary rotation.

Dr. RICHARDSON remarked that in all the cases he had reported the efforts at delivery of the head had been continued four or five hours before he saw the patients, and that in all cases the child was dead. There was no objection, therefore, to the consideration of craniotomy.

Dr. HOBGDON said he agreed with Dr. Richardson that it was extremely difficult if not impossible to deliver without craniotomy in this position. In his own experience of the process of version there seemed to be

a natural tendency in the head to come into the proper relations to the pelvic canal.

Dr. C. E. STEDMAN said that he had performed the operation at times when it seemed as if the child's face would slew round to the front in spite of his efforts to the contrary. He considered the position after turning to be the best for the performance of craniotomy, the occiput being pierced in this case.

Dr. RICHARDSON observed that from the moment of the beginning of traction on the feet, one should keep in mind the rotation, and that it was better to start early with the idea that the spine of the child should be kept forward.

Dr. SINCLAIR remarked that he considered it best to have a due regard all the time to the position of the head when it comes into the pelvis; and to this end to keep the body in an oblique position, with a tendency to turn to one side or the other.

PRIMIPARA; RETAINED PLACENTA DELIVERED BY HAND, WHICH WAS PASSED THREE TIMES INTO THE UTERUS, ONCE FOR DELIVERY OF PLACENTA, AND TWICE FOR REMOVAL OF CLOTS; PROTRACTED CONVALESCENCE, WITH REPEATED CHILLS AND FEVER ALTERNATING WITH DAYS OF COMFORT WITH NORMAL TEMPERATURE.

Dr. WELLINGTON read the case. See page 205.

Dr. Wellington further remarked, in answer to questions, that sweating occurred but once; that no malarial influence was known; that the patient took quinine largely and made a perfect recovery. He had entertained a supposition that a piece of membrane might have been left up in the contracted portion of the womb (as described in the written account) and that this might have exercised a remittent septic influence. He did not think hysteria a marked element in the case.

Dr. RICHARDSON thought it a good case for uterine injections.

Dr. SINCLAIR questioned if some moral influence had occasioned the symptoms, as in a case of his own.

Dr. INGALLS referred to the fact of the clot coming away while the woman was sitting up, and thought the symptoms might have been due to a small portion of clot or membrane or placenta retained.

Dr. ABBOT suggested that in that case there would probably have been some pain.

#### ABNORMAL MENSTRUATION, ETC.

Dr. RICHARDSON briefly mentioned two cases then at the Lying-in Hospital.

I. The case of a young lady waiting to be confined with her second child. She had a marginal attachment of the placenta, with hemorrhages. When not pregnant she had menstruated every two weeks since the age of fourteen; when pregnant every four weeks. The same peculiarity was observed during her first pregnancy.

II. Dr. Richardson had recently extracted the right central and lateral lower incisors of a child twelve days old. These teeth had become quite loose and were troublesome in nursing.

Dr. SINCLAIR said he had never heard of such a case of menstruation excepting as reported by Dr. Montgomery.

Dr. FORSTER remarked that he had observed a case of a lady who menstruated every four weeks during pregnancy and then gave birth to twins.

DR. RICHARDSON suggested that as the placenta was easily reached in this second pregnancy, in the case he just reported, the bleeding probably came from the lowermost point of attachment. The duration of the flow had been four or five days.

DR. WELLINGTON reported the case of a woman under his care, primipara, who was confined in the midst of an attack of pneumonia. She had had chills, and high temperature, and other symptoms of pneumonia, for three days, when labor came on. At the end of twelve hours, the head being low in the pelvis, and the pains subsiding, the child was delivered by forceps. The woman did not appear to suffer from the labor, but went on with the pneumonia and died upon the tenth day of that disease. There was no secretion of milk.

DR. SINCLAIR gave the account of a patient seventeen years of age whose pulse during menstruation was sixty or less, while in the intervals it was at the normal rate of from seventy-two to seventy-six. She kept about during the catamenia, which occurred rather too frequently but not too freely.

DR. FORSTER called attention to the article *phenyle* as an antiseptic, etc., effectual when used in the proportion of a teaspoonful to a quart of water, and very cheap. It was described as having a strong tarry smell. He had recently used it daily in a case of a sloughing fibroid successfully where a five per cent. solution of carbolic acid and thymol one to two thousand, had failed to overcome the offensive odor.

Using it after confinement all odor from the lochia was destroyed and patients had expressed themselves much pleased with it.

DR. NICHOLS, of Cambridge, mentioned the fact that stains in cloths, from permanganate of potash, could be instantly removed by a weak solution of sulphurous acid. The articles should afterwards be thoroughly washed in clean water to prevent injury to the fabric.

DR. RICHARDSON said that a one per cent. solution of chloral hydrate (De Paul's method) worked perfectly well as a uterine or vaginal injection for disinfection, continued till the fluid comes away perfectly clear.

### Recent Literature.

*Diseases of Women, including their Pathology, Causation, Symptoms, Diagnosis, and Treatment. A Manual for Students and Practitioners.* By ARTHUR W. EDIS, M. D., Lond., F. R. C. P. Philadelphia: Henry C. Lea's Son & Co. 1882.

It is a pleasure to read a book so thoroughly good as this one. It does not, perhaps, deserve so high a rank in respect to originality and research as others which might be named, but it thoroughly justifies the modest claim it makes of being "a manual for students and practitioners." The special qualities which are conspicuous are thoroughness in covering the whole ground, clearness of description, and conciseness of statement. It naturally follows that to write a book combining all these good points requires sound judgment in the selection of material. To know how to say enough on any one subject to give a clear idea of it, and at the same time to avoid useless discussion on points of interest it may be, but of little practical moment, is not always the gift of those who write books. Our author has excelled in this respect.

Another marked feature of the book is the attention paid to the details of many minor surgical operations and procedures, as, for instance, the use of tents, application of leeches, and use of hot-water injections. These are among the more common methods of treatment, and yet very little is said about them in many of the text-books. Dr. Edis lays down very definitely the indications for their use, and explains in detail the little points to be observed, at the same time not forgetting to point out the limitations of their employment, and the dangers of their abuse.

Where the general standard is so high it is almost superfluous to single out individual chapters for special comment, but there are one or two which, by their presence in a book by an English author, indicate a marked advance in this field. The chapter on Lacerations of the Cervix is exceedingly good. It gives the pathology of the lesion, the rules for preparatory treatment, and the various steps of the operation very clearly and precisely. The author has evidently a very decided opinion of the value of the operation, for he says, "Considering the good which it accomplishes it is remarkably free from risk, and when performed with care is, perhaps, the most successful one in uterine surgery."

He also describes the perineal body minutely, and recognizes its great importance in sustaining the uterus, and the necessity for its repair when ruptured. In the preface he claims to have treated the diagnosis of abdominal tumors "most exhaustively," and he certainly goes far towards carrying out his promise. The various forms of ovarian tumors are carefully differentiated, and then these in turn from the other abdominal tumors. Every possible condition which might be confounded with an ovarian tumor is considered, and we have careful rules laid down for distinguishing an ovarian cyst from obesity with tympanites, phantom tumors, ascites, parovarian cysts, hydatis, renal cysts, pregnancy, molar pregnancy, fibroids, and fibro-cysts of the uterus, encysted dropsy of the peritoneum, and a large number of other conditions.

Where so much is excellent, it seems almost invidious to point out the minor defects, but there are certain points which we wish had been touched upon. Very little is said as to the treatment of adhesions, and the most effective and at the same time safe method, namely, by systematic packing the vagina, is not alluded to.

So, too, with regard to pessaries. In general his rules for their use are very good, but we miss definite rules for measuring the vagina for pessaries, which are so necessary in one who would use them successfully. He advocates rather more freedom in the use of intra-uterine stems than seems safe.

In speaking of uterine hemorrhage he says that plugging the vagina in such cases is "unscientific and objectionable," but it seems to us that a method so safe and sure is on the contrary both scientific and free from objections. It is to be presumed that our author has not personally experienced the benefit of such a measure, or has imperfectly applied it.

On the whole, the book is one to be warmly recommended, especially to students and general practitioners, who need a concise but complete résumé of the whole subject. Specialists, too, will find many useful hints in its pages.

It is published in very good style, the type clear, and the illustrations for the most part very satisfactory.

**Medical and Surgical Journal.**

THURSDAY, FEBRUARY 23, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

**A METROPOLITAN SYSTEM OF DRAINAGE FOR BOSTON AND NEIGHBORING TOWNS.**

In his inaugural address to the Massachusetts legislature of 1881, Governor Long called attention to the increasing pollution of the Charles and Mystic basins, and suggested that some competent authority have power to arrange, or, at least, to report upon, a comprehensive system for draining the entire area embraced within a semicircle with a radius of ten miles from the State House at Boston.

This portion of the governor's address was referred to an appropriate committee, which, after much deliberation, introduced a resolve subsequently adopted by the legislature, authorizing the governor and council to investigate the whole question by means of a commission of experts, and report to the legislature of 1882.

A commission consisting of E. S. Chesbrough, C. E., Dr. H. P. Walcott, Dr. C. F. Folsom, of the National Board of Health, Hon. A. W. Boardman, formerly president of the Boston Board of Health, and Dr. Azel Ames, Jr., was at once appointed.

The commission has made its report, and with apparent unanimity advises the construction of a system of sewers for the relief of the Charles and Mystic rivers by intercepting the sewage of Boston, Brookline, Newton, Waltham, Watertown, Belmont, Arlington, Cambridge, Medford, Winchester, Woburn, Stoneham, Melrose, Malden, Everett, Chelsea, Revere, Winthrop, with a possible extension on one side to Dedham or Natick, and on the other to Lynn, and using for this purpose, so far as may be necessary, the nearly completed Moon Island sewer.

In place of the point of discharge for a north side sewer indicated by the Boston Commission of 1875, at Shirley Gut, a suggestion is here made, that the southwestern end of Deer Island would, for many reasons, be more desirable.

The growing attractions of this north shore as a place of summer resort, and the probable improvements at Point Shirley would both suffer from the erection of the works necessary for a discharge at this point, while Deer Island is the exclusive property of Boston, and offers an outlet into the most favorable current in the harbor, Broad Sound.

Upon the method of assessing the costs of construction, estimated at nine million dollars, excluding what has been already spent upon Moon Island sewer, there was evidently no substantial agreement in the minds of the experts. A table was presented of vari-

ous schemes of apportionment, which need only to be examined to be at once rejected.

The draft of an act to establish a metropolitan health district accompanies the report. As this act is to create the machinery for constructing and maintaining this system of sewers, we give a brief analysis of it. The towns and cities above named are made a corporation for the purpose of constructing and carrying on a system of intercepting sewers in the Charles and Mystic river basins, with such powers as are possessed by counties.

The work of this corporation is to be done by five commissioners appointed by governor and council, to whom also all plans must be submitted for approval.

The necessary funds are to be obtained in the same way as money is raised by counties. The corporation is not to interfere with drainage systems of towns except so far as to provide a proper outlet into the intercepting sewer, and is to have power to enforce such connections.

A useful chart is given upon which is laid out the line of the projected sewers.

This report has been the subject of two hearings at the State House before the Committee on Public Health; the towns included in the list were represented, and, with the exception of the five smallest, while opposed to the immediate adoption of the somewhat formidable act submitted by the experts, were all in favor of a continued examination of the subject with a view to the preparation of exact plans and definite estimates of cost.

The usual disposition to secure such legislation as would leave the State to pay the bill was met very ably by the State treasurer, who stated that the whole expense of the proposed sewer was covered by the amount of taxes collected from these cities and towns in one year, and that a district containing more than half of the whole valuation of the commonwealth, and more than a third of its inhabitants, needed no assistance from the State treasury.

With the peculiar situation of Boston, at the confluence of the Charles and Mystic rivers, certain to receive on the large area of neighboring flats all the foul matters held in suspension by the waters of two rivers becoming day by day more foul, some concerted action of the kind sketched in this act seems absolutely necessary, and fortunately for her, equally necessary for every town higher up on the two rivers. Cambridge may be indifferent to the filth which she believes is so discharged that it cannot return to her own shores, but is quite certain to protest against the fouling of the Charles by the Abattoir at Brighton or by the sewage of Newton.

Newton will look up the stream to watch Waltham and other towns, which, in turn, will care more for the purity of the stream above their limits than below them; and there is no point on the river where some strong local interests may not be secured to protect the stream. The very serious injury reflected upon Medford, last season, by the horrible condition of the lower Mystic basin, is even a stronger argument for thorough work in the Mystic valley.

The hearing brought out from the representative of the town of Woburn a capital statement of the difficulties in the way of securing proper drainage for his town, and a cordial offer to cooperate in any just plan for the relief of the valley.

The hearings as a whole were characterized by an honest recognition of existing defects, and an apparent willingness to undertake any well approved and equitable methods of relief.

#### PUERPERAL FEVER AND INFERIOR ORGANISMS.<sup>1</sup>

DISCUSSING the paths of entrance and of diffusion of the infection-germs of puerperal fever into the economy and its anatomical lesions, Dr. Doléris takes up (1) the wound, (2) the blood-course with its dependencies, (3) the lymph-course and the whole serous system. Under the first head local alterations connected with the infection are considered: for example, the so-called diphtheritic form which has a special origin, namely, the destruction of the anatomical elements by micro-organisms and the penetration of the germs through the Fallopiian tubes to the peritonæum.

(2.) The circulatory system. When a coagulum is formed beyond the physiological limit of the uterus, it is from a tendency to coagulation due to predisposition or to local lesions, atheroma or varices, — which explains thrombosis preceding phlebitis, — or it arises from alteration of the endothelium, analogous to endocarditis, due to colonies of micrococci fixed upon or in the walls of the vessel, which explains phlebitis preceding coagulation. The law of development of these organisms is the condition of absolute or relative repose. They do not multiply in the blood in movement, oftener they seem to perish there. If nothing favors the formation of the coagulum in the veins there is nothing but the hæmatic lesion. Thence come those profound dyscrasias, those anæmias which may be called pernicious by the same title as many others where the patients are prostrated a very long time. The principal result, then, of the introduction of micro-organisms into the blood, where their number is not excessive, is the special cachexia. In the special conditions already enumerated the result is thrombosis, phlebitis, endocarditis, emboli.

To the embolus succeeds the infarctus. In the putrid infarctus septic bacteria are found associated with micro-organisms in points or in chaplets. The purulent infarctus contains only micrococci or chaplets. The hæmatic lesion is of extreme importance since it sometimes bears all the cost of the malady, even death. Septicæmia may be characterized only by inappreciable lesions, but an alteration of the blood, evident, easy to discover, always exists. Nevertheless there is a slow septicæmia, a pyæmia, if you please (the author has no better word to stand for the old idea), very different from the first. That kills, this rarely terminates by death when it is not complicated by phlebitis or appreciable lymphangitis. The first will appear in severe epidemics, the second is frequent at

all times, and attacks many delivered in hospitals, whose disease evolves slowly after they leave, and often terminates, but with variable delays, by local and late accidents. It might be said that there was a thorn in the uterus, however small, which served as a feeding centre to the blood dyscrasia. True septicæmia, that which crushes almost from the outset of the disease, is characterized by the appearance of living organisms in the blood only at the last periods of life — sometimes even after death alone. The organism of this variety is of multiple form. It is made up of elements, elongated, slender, and having motion, which swarm in the tissues, the lymphatics, and peritonæum before death. To the blood they are admitted but tardily. These septic bacteria may take still other forms. The hæmatic lesions consist in an extreme alteration of the globules. The author thinks the lymphatics are the primary source of the septic bacteria, and that in those cases where severe septicæmia supervenes in the course of a less grave form, these bacteria begin to load the blood only when that element has become so deprived of oxygen by the action of other organisms as to enable them to flourish in it. In an extended form of septicæmia the blood always contains micro-organisms. In this form, which is the ordinary suppurative variety, the dyscrasic alteration of the blood is slow, and is effected by the presence of a special organism which may be considered specific; it is the micrococcus most perfectly represented by the chaplet of grains. In phlebitis with thrombus the presence of chaplets is not the rule.

Primarily the micrococci all penetrate from the lymphatics into the blood, and if they find the necessary conditions united in the veins they may determine suppurative phlebitis, but this is rare. Commonly the micro-organisms pass gradually into the blood without causing any other lesion than a more or less profound alteration of the globules. This slow alteration, if isolated from inflammatory lesions of the serous system, might be cured by appropriate means. The ordinary form is attended by these lesions which are foreign to the vascular system. Without these lesions the characteristics of this form are anæmia, the special dyscrasia and pyæmia, the blood globules enormously diminished in number, almost decolorized, and the leucocytes greatly augmented.

The nature of the organism differs in the different cases. When the lymphatic lesion coexists and develops progressively (the ordinary suppurative form) the culture of the micrococcus of the blood gives birth almost constantly to long chaplets of grains, just like those contained in the lymphatics, and sometimes to cylindrical bacteria. When the hæmatic lesion exists alone culture gives only micrococci in colonies, irregular groups or couples, but their organization, modified, perhaps, by sojourn in the blood, does not reach the stage of chaplets, which is a form already highly organized. When the hæmatic lesion is accompanied by phlebitis and infarctus the almost constant form is the point in couples, which is produced by cultivation in enormous quantities. The chaplet comes later if at all.

<sup>1</sup> Continued from page 186.

(3.) Under this head the entrance and diffusion of the germs by the lymphatic system to the serous membrane (joints, peritoneum, pleura, pericardium, cerebral meninges), to the glands, cellular tissue, skin, etc., are set forth, and it is asserted that, experimentally, the morbid germs are everywhere and always found, for example, in cases of post-puerperal, phlyctenoid erysipelas, in abscess, and in ecthyma.

It results from the *ensemble* of facts that lymphatic infection is first in point of time; that it gains the vascular system secondarily by the thoracic canal oftener than by other peripheral ways on account of the presence of glands as an obstacle; that it may reappear at points removed from the primary focus by reason of the connection of serous networks and blood capillaries.

Dr. Doléris follows Pasteur and divides the germs of infection into two grand categories:—

- (1.) Septic cylindrical bacteria (rapid septicæmia.)
- (2.) Micrococcus in form of chaplets (attenuated septicæmia).

Micrococcus in couples (suppuration). Micrococcus in points.

A considerable portion of the volume is devoted to records of cases of the different forms of puerperal fever aforesaid, details of autopsies, microscopic examinations of the fluids, and of the liquids of cultivation of the germs, and to the results of the inoculation of these germs upon various animals. The author seems to desire to hold himself rigidly to the demonstration of his facts, and to be wary of drawing conclusions not fully justified by these facts; recognizing that on many points much more elaborate investigations are yet required.

Taking up the subject of infection he discards the classification of auto-genetic and hetero-genetic infection, infection being always hetero-genetic. He would divide the modes of transmission into two classes:—

- (1.) Contagion by way of the uterine lesion; (2) and much more rare, contagion by other routes.

We cannot follow the author through his examination of the various means by which the disease is conveyed to the patient, accoucheurs, nurses, infants, instruments, sponges, cloths, etc. Among conditions affecting the air he specifies (1) the neighborhood of surgical wards of hospitals; (2) the existence of an epidemic characterized by affections whose nature, without being well elucidated, is generally considered to have numerous affinities with septicæmia. Such are erysipelas, lymphangitis from wounds, diphtheritic complications, septic cutaneous efflorescences, as ecthyma, etc. He discusses at some length the best known of these, namely, erysipelas. From certain facts he feels justified in concluding, not an absolute demonstration of the identity of erysipelas and puerperal fever, but that certain manifestations of erysipelas are only exterior lesions of local or general septicæmia with a tendency to extend along the course of the superficial lymphatics. The cause of these is the presence of a recognized septic organism proved to be capable of producing experimental disorders by inoculation.

Scarlatina is next considered in the same way; and

after separating the large proportion of scarlatinoid manifestations irregular and false, sometimes associated with puerperal fever, an absolute reserve is maintained concerning the relations of the two diseases until we shall be better informed upon the nature of scarlatina itself. Separation of the infant from the sick mother is advised. Receptivity and non-receptivity are discussed and illustrated; likewise the manner in which epidemics are created; and finally in the pathogeny of the work, infection by a route other than the lesion. In circumstances of excessive infection of the air Dr. Doléris considers it a positive fact that infection may proceed through the uterine mucous membrane during menstruation, through the digestive canal, and through the lungs. Observed facts lead him to believe that all that separates the suppurative form of puerperal fever, localized in the serous membranes, from cerebro-spinal meningitis or purulent fever, is the existence of the lesion in the former and its absence in the latter.

**THERAPEUTICS.**—The larger part of the twenty-six pages given to treatment has reference to prophylaxis. The author argues the superior advantages of hospitals under modern antiseptic regulations; and is sarcastic towards those who distrust carbolic acid, and who will use anything else in preference, asserting that a one-per-cent. solution is fatal to germ life, and that it is the best antiseptic in use. The three elements of rational antiseptic practice are stated to be:—

- (1.) Injection before delivery; (2.) Injection after delivery; (3.) Compress to remain over the vulva.

When factor of the lochia appears the questions arise: Is there a lesion? Is there retention of portions of placenta or membrane? Is there putrid decomposition of the lochia under the influence of the introduction of germs? In all these cases intra-uterine injections are required. If there be an exterior wound, antiseptic dressings. He does not believe that Zweifel or Bischoff have applied this method with sufficiently sustained severity. The multiplication of organisms and the decomposition of lochia should be rendered impossible.

He prefers the method of Fritsch, of Halle, three injections daily of two or three per cent. solutions of carbolic acid, rather than the more concentrated solutions and the uselessly repeated washings of Schücking or even the pulverizations of Spiegelberg, which are avoided by disinfection of hands and instruments, and especially by the compress during labor. Slowness, moderate force of the current, and the introduction of the tube into the uterus are three indispensable conditions of lavement practiced immediately after delivery. He urges immediate disinfection without waiting for the ordinary signs of decomposition of lochia. If delayed injections later are more difficult and dangerous, but not the less necessary if accidents of infection ensue, since they alone promise a real result. The sound with double current is the one recommended.

For internal treatment, since an attempt to eliminate the poison by the intestinal canal is forbidden,

he thinks the dominant indications are to prevent all abnormal movement of the abdominal viscera, and to hinder pelvic congestion. One per cent. carbolic lavements per rectum fulfill these indications. He would make exclusive use of such after delivery.

In view of the remarkable statistics of the Hôpital Cochin, Dr. Doléris mentions the methods always used by M. Champignonnière:—

- (1.) Antisepsis by carbolic acid solution.
- (2.) Sulphate of quinia, .80 to 2 grm., in the twenty-four hours.
- (3.) Salicylic acid, when particularly indicated, in ordinary doses.

- (4.) Blisters on the appearance of trouble.

In thirteen pages of appendix the methods of the writer's experiments are described.

We have extended the foregoing abstract to a length which leaves no space for remarks. It has seemed necessary to set forth somewhat fully the author's own researches and opinions upon micro-organisms at the expense of the total neglect of his interesting criticisms upon the work and views of others.

#### STILL ANOTHER ASYLUM CONFLAGRATION.

We clip the following from the *Boston Daily Advertiser* of February 22d:—

NEW YORK, February 21, 1882.—The Kings County Insane Asylum, a large structure of four stories, at Flatbush, L. I., was discovered to be on fire about six o'clock this morning. An alarm was promptly given and the Brooklyn fire department responded. During the fire some of the lunatics became greatly excited, and it was with difficulty they could be kept under control. A number of the more harmless were allowed to wander at will around the grounds. On the fifth floor there were twenty-six dangerous patients, and on the floor below forty-three patients in the same condition. Those who were helpless were carried on the backs of the nurses and attendants to the floor in the west wing. A man named Scoville perished in the flames, and an old paralytic was either suffocated by the smoke or died from fright. An attendant who became excited at the sight of the flames unlocked a gate on the north side of the building, and about a dozen inmates escaped. In two hours the flames were under control. The fourth and fifth floors of the east wing of the building were completely consumed, and the first, second, and third floors thoroughly drenched with water. The appliances for extinguishing fire at the asylum are entirely inadequate. There were 833 insane patients in the building, 333 of whom were in the east wing when the fire broke out. From the statements of the doctors and attendants it appears that the employees were more alarmed and excited than the other inmates, who behaved admirably. The loss on the building is estimated at \$30,000, on which there was no insurance. The burned building will be rebuilt immediately.

We regret to be so soon called on to chronicle another asylum fire, but we fear we shall have the same melancholy duty to perform on more than one future occasion. It does not seem to be in the nature of man, where fire is concerned, to take time by the forelock and thereby avert a terrible calamity.

The money loss was not large in the fire described above, and only two poor miserable lives were sacrificed, though the fatalities may have been greater, as a large number escaped; but one shudders to think how great the loss might have been had the fire broken out in a lower story, or had there been a fresh wind blowing. With demoralized attendants and a

building overcrowded with helpless inmates, the mortality under these circumstances would of necessity have been large.

Once more we beg insane asylum trustees to promptly organize a fire corps among the employees, not only for the purpose of doing efficient work in case of a fire, but also, by good discipline, to overcome the sudden paralysis of fear. At the same time let the stand-pipes, hose, water connections inside and out, and the fire extinguishers be looked to, to make sure that they are in good condition and ready for immediate use. These precautions require but little time, or money, yet they may save immense loss.

#### A CORRECTION FROM MR. KEITH.

We have received from Mr. Keith, of Edinburgh, some lines to the effect that statements contained in a letter published in the *JOURNAL* of January 12th, under the title of *The Meaning of Keith's Abandonment of Listerism*, do him very great injustice. Having much respect for Mr. Keith's remarkable and well-earned reputation as an ovariologist, we regret having given publicity to any statements which have caused him annoyance, especially as we are now informed they are not founded in fact.

We were assured of our correspondent's good faith, who in his turn thought himself assured of the correctness of his information. We hope before long to publish a detailed correction from Mr. Keith himself of any misstatements which may have unfortunately appeared in our columns. His attitude toward Listerism made a marked impression in the discussion at the Medical Congress in London last summer, and was noticed in the *JOURNAL* at that time in a letter from Professor Greene.

#### MEDICAL NOTES.

—Some of the newspapers in Philadelphia are much distressed by the recent grant of land by the city government to the University of Pennsylvania, which they term the university land grab.

—Dr. J. H. Raymond, who has been connected with the Health Department of Brooklyn for several years, has been appointed Health Commissioner of that city by Mayor Low. He was an efficient Sanitary Superintendent, and his appointment to his present office is considered an excellent one by those acquainted with the duties and difficulties of the position.

—The *Philadelphia Medical and Surgical Reporter* devotes an editorial to the danger of administering an anæsthetic without witnesses, and relates a case from the West in which a young lady was granted fifty thousand dollars damages against an old practitioner who had been the family attendant for three generations. On one of her visits he informed her that an operation was necessary, and induced her to take some anæsthetic. Subsequently, not improving, she consulted another physician, who told her

that she was pregnant. In due time a child was born. The lady made no effort at concealment, but in a short time brought an action for damages against her old doctor. He publicly denied the charge, but refused to go into court and do so under oath. After a few minutes' deliberation only, the jury brought in a verdict against the doctor, assessing the damages at fifty thousand dollars.

—A lecture was to be delivered on February 25th at the Town Hall, Kensington, London, on The Dress of the Period, under the auspices of the National Health Society. The lecture was intended to deal with the absurdities of modern clothing, and with the physical injury often caused by following the dictates of fashion.

#### PHILADELPHIA.

—It is proposed by several prominent fellows of the College of Physicians to establish a Nurse Registry Bureau at the College, on the plan of that conducted by the Boston Medical Library Association. It is expected that it will commence operations about the first of April.

—The Commencement Day at the University of Pennsylvania will be about March 13th, as usual; at Jefferson College, on account of the lengthening of the course, the Commencement will not be held until March 30th.

—At the Presbyterian Hospital Dr. Chas. H. Bennett conducts a course on Diseases of the Ear during the spring.

—A grand Charity Ball was given at the Academy of Music on Tuesday, February 7th, the receipts of which will be divided between the Hospital of the University of Pennsylvania, Jefferson College Hospital, and the Wells Eye Hospital. It is said that the net receipts were in the neighborhood of twelve thousand dollars.

The Annual Address before the Academy of Surgery was delivered by Prof. D. Hayes Agnew on Monday evening, February 6th, in the lecture room of the College of Physicians; his subject was A Sketch of the Life and Writings of Baron Larrey. The regular meetings of the Academy are held on the first Monday evening of each month, and are well attended.

—The Seaside House for Invalid Women at Atlantic City, New Jersey, that has for several years been doing good work during the summer season, has just been thoroughly prepared for occupancy during the winter and spring months. It now offers most comfortable accommodations for women of moderate means who need the rest and reinvigorating influence of a residence at the sea-shore. The institution is one of Philadelphia's charities, and its board of managers is composed of well known ladies and gentlemen of this city. Dr. Wm. H. Bennett of Philadelphia is the attending physician during the summer, and Dr. Boardman Reed, of Atlantic City, during the fall, winter, and spring. Any invalid woman of good character can be admitted into the institution, and have either a room to herself or a single bed in a room with another; in the latter case the charge is five dollars per week; when a patient has a room to herself it is from

eight to ten dollars per week, this including board, nursing, medicines, and medical attendance; it is to be paid in advance to the lady in charge. Tickets to the seashore are furnished at a reduced rate on application to Dr. W. H. Bennett of Philadelphia.

—At the Pennsylvania Hospital the Dispensary Department, established some five or six years ago, is now in a very active state. Instruction in minor surgery has been carried on for several years in connection therewith by Dr. Chas. I. Hunter and Dr. Wm. Ashbridge. Drs. Geo. C. Harlan and Chas. H. McIlvaine, in order to utilize the material in attendance, have opened a course of practical instruction in Ophthalmoscopy and Refraction and in the Treatment of Diseases of the Eye and Ear, to be given only to graduates in medicine.

—Dr. L. S. Pilcher of Brooklyn having accepted an invitation by the directors of the Philadelphia County Medical Society to read a paper on the 8th of March, it is expected that a social meeting of the Society will be held after the meeting, to give him a reception.

#### Dischlam.

#### AN ANOMALOUS CASE. — WAS IT VARIOLOID?

MR. EDITOR, — The following case puzzled me somewhat, and may interest the readers of the JOURNAL: —

C. D. J., student, aged eighteen. Previous health good. Says he has always had heart disease. On examination, a well marked aortic regurgitant murmur was detected, with pulsating carotids. Acne on face. Says he had measles four years ago.

Was vaccinated January 24th, and again February 1st, with negative result.

February 2d attended a ball where were people from several towns. After dancing walked a little way to the supper hall in slippers and without an overcoat. Was as well as usual until February 5th, then had a headache and general malaria. On the next day, February 6th, complained of backache, and thinks he had fever. On the 7th felt chilly all day, but no real chill; at night took a "sweat;" no appetite.

The next day, the 8th, these symptoms were increased. I saw him for the first time on the following day, Thursday, the 9th. He then complained of severe pain in the back and loins, which was the most emphasized symptom. His eyes pained him, and were red and injected; he had also abdominal pain. Temperature, 103° F.; pulse, 60.

There was also an erythema, resembling that of ru-beola, on his wrists, back of his hands, and abdomen. At my evening visit the temperature was somewhat over 103° F. Friday, the 10th, temperature 101.4° F. in the morning; 103.4° F. in the afternoon; pulse, 60; respiration, 32 to 36. The eruption was now well marked, extending over the whole body, particularly abundant on the abdomen, back, lateral surfaces of trunk, feet, and hands, with a few spots on the face, scalp, eye-brows, and nose. He complained also of sore spots under the tongue and on the inner surface of the cheeks and lips. On examination of the latter small whitish round spots were seen, with reddened areola; fauces red and congested; backache very se-

vere; also headache, but not a marked symptom; abdominal pain; eyes inflamed; moderate photophobia; tongue with thin white coat, red at edges and tip with projecting papillae; mouth dry. Said he had epistaxis last night; no catarrh.

Saturday, the 11th, temperature,  $102^{\circ}$ , A. M.;  $103^{\circ}$ , P. M.; pulse, 68; respiration, 28. Backache not so severe; other symptoms much the same. Complained of his right knee being swollen and painful. On examination there was puffiness and possibly some effusion. Was called in the night on account of severe epistaxis.

Sunday, the 12th, temperature,  $100.5^{\circ}$ , A. M.;  $101^{\circ}$ , P. M.; pulse, 60; respiration, 28. No change in the eruption; slight itching on the face; other symptoms much improved, except his eyes; continued photophobia; no complaint from his knee; two slight attacks of epistaxis during the day.

Monday, the 13th, temperature normal; pulse, 52; respiration, 28; eruption fading; feels very comfortable; spots in his mouth disappearing.

Tuesday, the 14th, temperature normal; pulse, 48; respiration, 24; eruption rapidly disappearing; no pain or discomfort.

Wednesday, the 15th, temperature normal; pulse, 50; respiration, 28; convalescent; eruption hardly visible; tongue cleaning.

The next day he went home. He came to see me on his return, the 20th of February, and reported himself as well as usual, with the exception of some weakness of the eyes. I have also learned that a young lady who attended the ball, and also visited the house where the young man was sick, had a similar eruption, though not so extensive or well marked, for a day or two, with no constitutional symptoms.

The case seemed to me a peculiar one, resembling, in many of its symptoms, varioloid: the intense backache, eruption of the mucous membrane of the mouth, photophobia, the swelling of the knee, and in many of the other general symptoms. On the other hand, the only means of exposure seemed to be at the ball, February 2d, which gives but four days for incubation. Then, also, the character of the eruption, a simple erythema, and its rapid disappearance. A practical point in it is, Should it have been reported at the time of the appearance of the eruption as a doubtful case of varioloid, and quarantine enjoined? Very truly yours,

EDWARD O. OTIS, M. D.

EXETER, N. H.

#### CONSUMPTION IN NEW ORLEANS.

DR. J. B. ELLIOT, of the University of Louisiana, recently read an interesting paper before the New Orleans Auxiliary Sanitary Association, upon the prevalence of consumption in New Orleans in connection with the excessive amount of soil moisture which prevails there.

He points out that among the chief causes of the mortality of that city, consumption not only ranks first of all, but that it nearly doubles, as a cause of death, either yellow fever, malarial fever, or diarrhoeal diseases. The total number of deaths in New Orleans, from all causes, for the years 1869 to 1879 inclusive, were 73,796; deaths from consumption, 8,493; from yellow fever, 4,935; from diarrhoeal diseases, 4,813; from malarial fever, 4,521. It has been asserted that this excessive mortality from consumption is caused by

persons who have contracted the disease in the North, and come to New Orleans during the winter. This has been shown to be incorrect by Dr. Chaillé, who argued that if this was the true explanation the deaths from consumption during the colder months should greatly exceed the deaths during the six warmer months.

Now the statistics show that the number of deaths from consumption during the six colder months, for the eleven years, were 4,055; of deaths during the six warmer months, 4,438; showing that the excess of deaths from consumption in New Orleans occurred during the six warmer months.

He says: "We must accept the conclusion that consumption is by far the most formidable cause of death which we have to deal with in New Orleans. In the light of the researches of Drs. Bowditch and Buchanan, we have not far to go to discover the conditions which produce it.

"If soil moisture and consumption are related as cause and effect, then we would expect to find, as we do find, that that disease is the curse of our city, and that its excessive occurrence is due chiefly to the fact that the water level in the soil is coincident with the surface of the soil.

"The remedy for such a condition is plain. We are a community suffering from topographical conditions that we must use our common sense to conquer. Common sense tells us that, as we cannot — for many years at least — sink the water to a lower level in the soil, we must lift our habitations to a higher level above the soil. The proper methods for accomplishing this have already been pointed out and insisted upon by the sanitary authorities of our city, and we may feel reasonably assured that they will be enforced in all buildings hereafter erected. But in those buildings already in existence, where the evils of water under the lower floors, and wet lots below the street level, exist, we can only hope for a correction of the fatal conditions by teaching our fellow-citizens to insist upon their correction before they rent or lease. When property-holders learn that the value of their possessions will depend upon the absence of these conditions, then we may hope for their speedy removal." — *Sanitary Engineer*.

DR. JOSHUA TUCKER.

At the monthly meeting of the American Academy of Dental Science, held in Boston, January 4, 1882, the following resolutions were unanimously adopted: —

*Resolved*, That the American Academy of Dental Science has received with sincere sorrow the intelligence of the death of our late beloved friend and associate, Dr. Joshua Tucker, of Boston, an honorary member and former president of this Society. He departed this life November 7, 1881, aged eighty-one years and three months.

*Resolved*, That in the decease of Dr. Tucker this Academy has been called to mourn the loss of one of its most valued members, one whose ability, integrity, genial manner, and kindness of heart endeared him to all whose privilege it was to be associated with him.

By his death another distinguished name is added to the list of those early pioneers in dental science who have finished their earthly labors and passed on to the land of rest and immortality, and whose memory the profession will ever delight to honor and cherish.

*Resolved*, That this Academy will never forget the deep interest and untiring devotion which our late friend invariably brought to the performance of his duties during his long and successful professional life, embracing a period of more than fifty years. Dr. Tucker was one of the first in this country to take a high stand in the practice of his profession, which he always maintained; and throughout his whole career his actions

were characterized by an enlightened sense of the responsibilities which rested upon him, both in his relations with the profession and with those who were placed under his care and treatment, thus proving his constant desire to be faithful to the trust reposed in him. This patients as well as the profession will hold him in grateful remembrance.

*Resolved*, That our sympathies and condolence are extended to his widow and other relatives in their bereavement, and we would also rejoice with them that he was permitted to live to

such an advanced age, and that he has left so beautiful a record of a long and useful life.

*Resolved*, That these resolutions be entered upon the records of the Academy, and that the secretary be instructed to transmit a copy of the same to the widow of the deceased; also to the dental and medical journals for publication.

GEORGE T. MOFFATT,  
JACOB L. WILLIAMS,  
EDWARD S. HARRIS, } Committee.

# REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 18, 1882.

Deaths reported 2641 (no reports from Philadelphia, New Orleans, and Cleveland): 1090 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 691, consumption 356, lung diseases 413, scarlet fever 186, diphtheria and croup 172, small-pox 100, typhoid fever 56, measles 51, diarrheal diseases 36, whooping-cough 27, cerebro-spinal meningitis 18, erysipelas 18, puerperal fever 17, malarial fevers 14, typhus fever one. From typhoid fever, Chicago 12, Buffalo eight, New York and Baltimore five each, Cincinnati and District of Columbia four each, Pittsburgh three, Boston, St. Louis, Milwaukee, Holyoke, and Newton two each, Brooklyn, New Haven, Nashville, Salem, and New Bedford one each. From measles, New York 37, Chicago six, Brooklyn three, Buffalo and New Haven two each, Taunton one. From diarrheal diseases, New York 17, Brooklyn and Baltimore three each, St. Louis, District of Columbia, Pittsburgh, and Providence two each, Chicago, Buffalo, Nashville, Lowell, and Newton one each. From whooping-cough, New York 14, Brooklyn and Chicago two each, Boston, Buffalo, Worcester, and Fall River one each. From cerebro-spinal meningitis, New York 10, Buffalo two, Milwaukee, Nashville, Worcester, Fall River, Springfield, and Spencer one each. From erysipelas, New York six, Brooklyn

four, St. Louis and Springfield two each, Chicago, Boston, Cincinnati, and Buffalo one each. From puerperal fever, Milwaukee four, Boston three, Brooklyn, Chicago, Cincinnati, and Lowell two each, Pittsburgh and Worcester one each. From malarial fevers, New York eight, Chicago four, St. Louis and Springfield one each. From typhus fever, New York one.

Seventy-four cases of small-pox were reported in Cincinnati, Pittsburgh 72, Baltimore 10, Brooklyn nine, Holyoke four, Pittsfield three, Boston two, District of Columbia two, and Milwaukee two; diphtheria 38 cases, scarlet fever 10, typhoid fever seven in Boston; scarlet fever 15, and diphtheria nine, in Milwaukee.

In 43 cities and towns of Massachusetts, with a population of 1,095,005 (population of the State 1,783,086), the total death-rate for the week was 19.85 against 20.16, and 20.60 for the previous two weeks.

For the week ending January 28th, in 173 German cities and towns, with an estimated population of 8,304,484, the death-rate was 26.2. Deaths reported 4190; under five 1932; pulmonary consumption 592, acute diseases of the respiratory organs 440, diphtheria and croup 237, diarrheal diseases 149, scarlet fever 92, whooping-cough 74, typhoid fever 46, measles and röteln 44, puerperal fever 19, small-pox (Königsberg, Hamburg, Solingen) three, typhus fever (Thorn, Berlin) two

The death-rates ranged from 16.9 in Cassel to 43.8 in Essen; Königsberg 25.1; Breslau 31.1; Munich 33.7; Dresden 24.8; Berlin 23.7; Leipzig 24.4; Hamburg 29.9; Hanover 22.9; Bremen 21; Cologne 29.1; Frankfurt 23.8; Strasburg 28.1.

In the 28 English towns, with an estimated population of 8,455,308, for the week ending February 4th, the death-rate was 24.9. Deaths reported 4042: acute diseases of the respiratory organs (London) 647, whooping-cough 273, measles 92, scarlet fever 91, fever 49, diarrhoea 39, diphtheria 34, small-pox (London 13) 17. The death-rates ranged from 8.4 in Halifax to 32.2 in Plymouth; Bristol 16.4; Sheffield 21.4; Manchester

21.9; Birmingham 22.2; Leeds 26.1; London 27.1; Liverpool 28. In Edinburgh 19.3; Glasgow 22.4; Dublin 37.6.

For the week ending February 4th in the Swiss towns there were 50 deaths from pulmonary consumption, acute diseases of the respiratory organs 40, diphtheria and croup 17, whooping-cough 10, diarrhoeal diseases 13, typhoid fever five, puerperal fever four. The death-rates were, Geneva 33.1; Zurich 31.3; Basle 22; Berne 34.5.

The meteorological record for the week ending February 18th, in Boston, was as follows:—

| Date.            | Barom-eter. | Thermom-eter. |          |          |            | Relative Humidity. |             |       |            | Direction of Wind. |             |            | Velocity of Wind. |             |            | State of Weather. <sup>1</sup> |             |                       | Rainfall.         |  |

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 18, 1882, TO FEBRUARY 24, 1882.

FINLEY, J. A., captain and assistant surgeon, Fort Adams, R. I. Granted leave of absence for one month. S. O., Department of the East, February 20, 1882.

RAYMOND, H. L., first lieutenant and assistant surgeon. Relieved from duty at the Presidio of San Francisco, and assigned to duty at Alcatraz Island, Cal. S. O., 28, Military Division of the Pacific and Department of California, February 15, 1882.

THE SECTION FOR CLINICAL MEDICINE AND PATHOLOGY OF THE SUFFOLK DISTRICT MEDICAL SOCIETY will meet at 19 Boylston Place, on Saturday, March 4th, at 7.45 P. M. The following papers will be presented: Dr. F. Minot, A Case of Chorea treated by Arsenic. Dr. F. C. Shattuck, Unintentional Aspiration of the Liver. Dr. T. M. Rotch, A Case of Intussusception, with Specimen. Dr. G. M. Garland, The Pleuritic Stitch. ALBERT N. BLODGETT, Secretary.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting of the Society will be held on Monday evening, March 6th, at eight o'clock, at the Medical Library, 19 Boylston Place. Reader, Dr. Webber. M. H. RICHARDSON, Secretary.

CORRECTION.—The residence of Dr. W. H. Baldwin, page 176 of the JOURNAL (February 23), should be Alabama, and not South Carolina.

BOOKS AND PAMPHLETS RECEIVED.—An Index of Surgery, being a Concise Classification of the Main Facts and Theories of Surgery. For the Use of Students and others. By C. B. Knley, F. R. C. S., Senior Assistant Surgeon to the West London Hospital, etc. New York: Birmingham & Co. 1882.

Preliminary Observations on the Pathology of Sea Sickness. (Reprinted from The Lancet.) By J. A. Irwin, M. A. Cantab., M. D. Dublin. Philadelphia: P. Blakiston, Son & Co. 1881.

Removal of a Cyst of the Pancreas weighing twenty and one half pounds. Dr. N. Bozeman.

Transactions of the American Ophthalmological Society. Seventeenth Annual Meeting, Newport, 1881. New York: Published by the Society. 1881.

Vaccination. Advice on the Necessity of Vaccination; the Value of Vaccination; the Tests of Successful Vaccination; How often Revaccination should be Done; the Quality of Vaccine; the Best Way to Use Vaccine; How to Prevent and Exterminate Small-Pox, etc. Issued gratuitously by the North Carolina Board of Health.

Contributions to Orthopaedic Surgery. By Charles F. Stillman, M. D., of New York. A New System of Surgical Mechanics. Reprinted from Transactions of the American Medical Association for 1881.

Marriage and Parentage and the Sanitary and Physiological Laws for the Production of Children of Finer Health and Greater Ability. By a Physician and Sanitarian. New York: M. L. Holbrook & Co. 1882.

Human Osteology, comprising a Description of the Bones, with Delineations of the Attachments of the Muscles, the General and Microscopic Structure of Bone and its Development. By Luther Holden, assisted by James Shuter, F. R. C. S., Assistant Surgeon to the Royal Free Hospital. With numerous Illustrations. Sixth Edition. Philadelphia: Presley Blakiston. 1882.

Illustrations of Dissections in a Series of Original Colored Plates, the Size of Life, representing the Dissection of the Human Body. By George Viner Ellis, Professor of Anatomy in University College, London, and G. H. Ford, Esq. The Drawings are from Nature by Mr. Ford, from Dissections by Professor Ellis. Reduced on a Uniform Scale and reproduced in facsimile expressly for Wood's Library of Standard Medical Authors. Vol. II. Second Edition. New York: William Wood & Co. 1882.

Recherches cliniques et anatomico-pathologiques sur les Affections cutanées d'Origine nerveuse. Avec 4 Planches en chromolithographie et plusieurs figures intercalées dans le texte. Par Henri Leloir. Paris: Aux Bureaux du Progrès Médical. 1882.

Annual Reports of the Officers and Managers of the New Jersey State Lunatic Asylum at Trenton for the Year ending October 31, 1881.

Fourth Annual Report of the Connecticut State Board of Health for the Fiscal Year ending November 30, 1881, with the Registration Report, 1880, relating to Births, Marriages, and Deaths. Printed by order of the Legislature.

The Transactions of the American Medical Association, instituted 1847. Vol. XXXII.

## THE DIAGNOSIS OF POTT'S DISEASE OF THE SPINE BEFORE THE STAGE OF DEFORMITY.

BY V. P. GIBNEY, A. M., M. D.,

*Of the Hospital for the Ruptured and Crippled, New York.*

ONE hundred and ninety-six cases of Pott's disease of the spine came under treatment in the out door department of the hospital during the year ending December 31, 1881, and of this number only fourteen came without any angular deformity. Six of this number were cases wherein the cervical region was alone involved, the remaining eight being equally distributed between the dorsal and, the lumbar regions. We have, then, one hundred and eighty-two new cases of angular deformity from this disease in a single year.

This is my apology for the paper, and the present seems a fitting time to talk plainly and to urge upon the general practitioner, be he physician or surgeon, be he specialist or not, the vast importance of making a diagnosis early and before the mother or the nurse calls attention to the significant knuckle. It requires no professional skill to diagnose the disease then. The drift of teaching, I fear, within the past seven years, has been rather toward treatment than toward diagnosis. The cry has been for therapeutics, and the cry has been heard.

Many a case of rickets and of simple antero-posterior curvature from anemia has been encased in plaster-of-Paris from lack of proper diagnosis, and yet caution forbids us condemning the practice. If the treatment will prevent deformity it is better to err on the safe side. It is an outrage on Science, however, to report such simple cases as Pott's disease and as cured by this or that plan of treatment.

A friend, whose teachings I value very highly, is reported to me as declaring in his lectures that the physician who cannot diagnose vertebral caries before the stage of deformity has no right to practice medicine. That professor is not an orthopaedic surgeon either. I am not as yet prepared to adopt that speech as my own. There is much teaching on this subject that is actually vicious, but some signs formerly laid down as pathognomonic are not any longer urged as of any practical importance. I speak more particularly of tenderness on pressure over or percussion of the spinous processes. Nothing is to be gained by this procedure and a persistence in it often irritates the little patient to such an extent that a good examination is rendered practically impossible.

It may be laid down as a rule, with barely enough exceptions to prove the rule, that tenderness on pressure either with the hand or with the hot sponge is never present in the early stages of a vertebral osteitis. So that in searching for an incipient caries let no reliance be placed on such a fallacy. I have in mind now a patient who did present tenderness early, but this was a female child and it is not at all unlikely that this was but the sign of a hysterical spine complicating the bone disease. Pressure over the spine posteriorly ought rather to relieve than cause pain where the bodies of the vertebrae are enlarged by recent inflammatory changes. The patient naturally carries himself in lordosis and that which aids this position gives relief. A weak or soft spot (apparently soft) is

sometimes found by firm pressure along the spinous processes in rachitic children. Within the past three months two very intelligent families from different parts of the country have brought their children for mechanical treatment, and after an exceedingly tedious examination I failed to find any spinal disease. The parents came, it is true, without any letter or card from the physician in attendance, but were very positive in stating that he had discovered a weak, or soft, spot, (pointing to a spinous process in the dorsal region) and had urged them to take the child without delay to the city for a brace.

Another test, very popular and constantly employed, I want to raise my voice against, for the reason that the abuse is so easy and the use even is unsatisfactory. It is the forcible pressure with the hand or blows with the same on the top of the head or shoulders in the long axis of the body. If the upper dorsal or the cervical region be affected this is actually dangerous, and it is not only true of recent cases but all the more true of cases that have been under treatment for a time. The expedient is resorted to then to ascertain whether or not a cure has been established.

A few months ago I was on a visit to a friend in a neighboring town, and the mother of a patient little girl, terribly deformed, was my hostess, and while discussing that topic, ever supreme in her mind, said, "Dr. Gibney, I don't know now, with all my fund of experience, to whom I should go if my little girl were just beginning her sufferings." And she had had a varied experience in therapeutics, for her wealth had commanded distinguished talent.

The history she gave me was that when her daughter, now fourteen years of age, was only four she began to manifest signs of weariness on slight exercise, would seek various attitudes which would rest the spine, in fact, presented symptoms that persisted until nearly three months had elapsed, when a small "knuckle" was observed between the shoulders. An orthopaedic surgeon was consulted, and he took the case immediately under treatment. For one year his skill and his assiduity were all that the most exacting parent could demand. His aim was to arrest the disease, and to prevent any further deformity, and his aim was certainly unerring. After a year's treatment he allowed the little patient to stand on its feet, removed the apparatus, and, in the presence of one or two members of the family, placed his hands on the child's head, firmly pressing downward. He was no feeble specimen of a man, and the weight upon that tiny head was more than it could bear. The patient winced under this crucial test, the limbs trembled all that day, and a restless night followed. Pain was felt in the back of the neck, and along the spine, and in remote parts of the body. Several days of irritation followed, the "knuckle" began to increase in size forthwith; the doctor was greatly annoyed that the case should act in this way, his interest seemed to wane, and in three months another specialist was consulted, under whose mechanical treatment the child became paraplegic. He, skilled as he was, got the credit of producing the paralysis, and other advice was sought. For several years the loss of power continued, the deformity grew into an immense boss, and finally, on the return of power, abscesses made their appearance.

Now, I have not pictured this case to censure any one; I have simply narrated it to serve as a warning. It made a profound impression on me, for I had so

often seen that "pressure test" employed, and in my earlier experience had practiced it myself. It is refreshing to read the remarks made by Mr. Howard Marsh in the *British Medical Journal* for June 11, 1881, concerning these same dangerous experiments. His paper is full of valuable instructions, and I cannot too strongly urge its close study.

The truth is that the nearer one comes to a knowledge of the pathology of the disease now under discussion the more easily can a diagnosis be made, and the more rational will be the interpretation of the symptoms. As Mr. Marsh says, we do not want to talk about *angular curvature*, or curvature of the spine. The term *spondylitis*, which some of my friends are attempting to introduce, is a confusing one to the student in pathology. That term was first employed, and is now employed, to designate a kind of arthritis deformans, the lesion being a rheumatic form of inflammation affecting the lateral masses and spinous processes, and never the bodies of the vertebrae. It is characterized by increase rather than by destruction of tissue. Julius Braun published, in Hanover, in 1875, a monograph on this affection as one of the most frequent causes of manifold neuroses, especially spinal irritation. He published fifty-eight cases, and drew a sharp distinction between this and spondylarthrocase (spinal caries). In spondylitis we get very marked spinal tenderness.

If we understand that a very large proportion of all the cases of Pott's disease, especially in children, begin as a central otitis of one or more of the bodies of the vertebrae, and understand that this otitis is attended with swelling in the early stages, we can then understand the mechanical effect on nerves passing through the foramina of exit when any concussion or contortion by accident occurs.

There are certain general questions to be settled in examining a case, and the first and most important is *the duration of the symptoms*. If we find the patient has been suffering vague and irregular neuroses for a fortnight or longer without any complete cessation of the same, we must know next *the behavior of the child at play or when getting into and out of bed*. If a slight strain or jar occur while the little one is at play this will be followed by an oral expression of pain, and relief will be sought in that position which will give rest to the spine. The mother, if you give her an opportunity, will tell you of many attitudes intuitively assumed. You need to know then *how the sleeping hours are passed*, and if you learn that instead of sharp screams without waking (so peculiar in hip disease) a moaning or restlessness with little cries on turning have been observed, then let the patient be stripped naked, and while this is being done the time can be spent profitably in getting the family history. I do not mean the reply to the questions, "Are you healthy?" and "Is your husband healthy?" You waste valuable time in propounding such questions. Ascertain all that there is to learn about transmissible diseases in both members of the family by direct and cross examination. A knowledge of facts need not bias your judgment. Learn also the personal history of the patient. If any cholera infantum followed by a slow recuperation, if rickets with its significant malnutrition, if malarial fever, if the more prominent of the exanthemata, such as scarlatina or diphtheria, if *whooping-cough* with tardy convalescence, — if any of these diseases, I say, come to your knowledge in getting the

personal history (and it is the safer to ask about them all) you will be about ready to give an opinion. I say *about ready*, because if you have obtained any facts leading you to recognize an acquired or hereditary diathesis, you will already have observed the movements of the child as it moves over the floor. You will also have already heard about a fall or injury, the knowledge of which came second-hand to the mother after she began to observe the very first symptoms of disability. Of course you will investigate the reported injury, and while I am as willing as any one to give a fall all the credit it deserves in the aetiology of joint diseases, I must insist on getting facts with regard to falls even.

One among the first things to observe is how the patient walks, whether the spine is carried stiffly, and whether it appears shifted to one or the other side of the pelvis. You will then observe the stooping, whether the spine be held erect, or nearly so, while the thighs and legs, by sharp flexion alone, execute the act. And do you know there are some children who wear one's patience out before you can get them to stoop? You sometimes have to lay them down forcibly. They will surely not remain on the floor, and you can get much information by watching them roll over and get upon their feet again. You will see the child often, while standing, place the hand on one or the other thigh for the "collateral transmission" of weight. The functions of both hips should be carefully examined, the pelvis should be explored by palpation and percussion as well as the ilio-costal spaces. So much for the general examination of a case for Pott's disease before the stage of deformity. A few details now regarding the different regions.

#### I. THE CERVICAL AND CERVICO-DORSAL.

One among the earliest symptoms observable in patients who are developing disease in the bodies of the cervical or upper dorsal vertebrae is a slight torticollis or a modified opisthotonos. The child early shows a disinclination to hold the head erect or to do anything which requires rotation of this member. If any object excites the interest the whole body will turn in getting a view. Often the opisthotonos will be apparent rather than real. The head will be held in this position to prevent the chin falling toward the sternum. Besides it calls other muscles into play in giving support. This can be easily excluded from true torticollis. In the one passive movements of the head are resisted and are painful, all the muscles coming to the rescue to prevent any motion that may aggravate the sensitive nerves; in the other there is no pain unless you make traction on the shortened or contracted muscles. The muscle will usually stand out in bold relief, and there is an element of rotation here not present in the other case.

The facial expression — that of pain and extreme caution in movement — is very significant. The gait is likewise peculiar, the steps being short and cautiously taken, and then there is the compensating backward curve in the dorso-lumbar region which often misleads one into regarding this as the affected locality. This position of the shoulders, shrugged as it were, the head seeming to sink down into them, is significant. The little hands can often be seen grasping the chin or the side of the head so as to support as steadily as possible. These signs and these manœuvres once seen will not be forgotten. There will be a history of pain,

usually, in the prone position, the mother will tell how sensitive the head is, will tell how much pain and distress follows the slightest cough. Indeed, occipital neuralgia will almost always be present if the first or second cervical vertebrae are at all affected either primarily or secondarily, for the sub-occipital and the great occipital nerves emerge in this region. Mr. Marsh makes a very good point when he observes that in other regions of the spine pain, when it is present, is felt either at the affected part or below it and is very rarely situated at a higher level. Irregular action of the diaphragm will materially assist in making a topographical diagnosis, for the fourth and fifth cervical pairs must necessarily be implicated by reason of the pressure from inflammatory products.

The ordinary temporary deformities of the head and neck from cold sometimes puzzle one in making a differential diagnosis, but in these we have exaggerated deformities with histories of a brief duration. An examination of the tonsils and pharynx is always necessary, and in children it is often very difficult to satisfactorily explore these parts; yet the presence of hard or soft tumors along the post-pharyngeal walls can easily be recognized by the finger. If any doubt exists this exploration should not be neglected. An abscess in this region will sometimes produce the most alarming laryngeal spasm.

The symptoms already detailed apply more particularly to the disease as it affects infants and children. In adults we can get better examinations, we can ascertain more definitely the location of pain. Furthermore, caries of the cervical spine in adults usually follows some severe traumatism, as a fracture or a subluxation, for instance.

## II. THE DORSAL VERTEBRÆ.

When the osteitis is confined to this region, the head symptoms already described are wanting and the pain is referred to parts on a level with or below the vertebrae involved. For instance, in the upper dorsal the intercostal muscles are impaired in function and the respiration is generally abdominal. Lower in the column we have abdominal pains and a fondness, very marked, for the prone position. This is sought by day over the mother's knees, over a chair, or on the floor; and by night this position is naturally assumed. To differentiate from the pains due to intestinal disorder, such as the presence of worms in the alimentary canal, or to malarial poisoning, is often difficult, that is, if one do not always examine a case thoroughly. It is well known to the practitioner who lives in malarial localities that "pain in the stomach" is one of the most constant symptoms in children suffering from this poison. I well know that a single examination will not always enable one to pronounce positively in a given case, but I do know that we have a specific that will enable one to eliminate malarial poisoning, and the reason why many cases of dorsal caries are not recognized in their incipency is not because the attending physician lacks skill but because he fails to apply that skill. He feels so confident that the case is malarial that he prescribes without a physical examination, without even an inspection, and with the full assurance that he is correct he does not examine the case again. He does not know, perhaps, that chronic bone diseases are notably diseases of exacerbations. I care not how great a man may be, how vast his experience may have been, the necessity still exists for a careful examina-

tion of all children who have abdominal pains with or without remissions.

The spine will present, instead of a projection backward or a fullness even, rather an incurvation — a lordosis, and this, taken in connection with the duration of the symptoms, the detailed history, the rigidity with which the column is held, the peculiarity in walking and in stooping, will enable one to make at least a provisional diagnosis of vertebral osteitis and give the patient the benefit of precautionary treatment.

One cannot always rely on failing health as a symptom, for there are many cases of unmistakable bone disease in fat, hearty-looking children. The plan of making extension with the child lying prone across the examiner's lap, and then reversing this, so often practiced and recommended by some good teachers in orthopedic surgery, does not meet my hearty approval. I resort to it by way of routine, but I must confess I have never been able to extract much information therefrom. As above remarked, the way in which the patient gets up from any decubitus is very significant, and the face will tell where the disease is located.

In the lower dorsal tumors in either ilio costal space often present before any bony deformity can be recognized, and we must bear in mind that a perinephritic abscess will give rise to the same sign. In the former, however, we can generally get a history of chronicity, while in the latter the symptoms will be of short duration and have a sudden onset. In adult life we have strains and rheumatism from which to differentiate, and I do not know of any infallible signs by which one can always be guided. Let the functions of the spine be thoroughly examined, and if possible get a history. Without this latter it is frequently impossible to reach a conclusion at a single visit. In all cases, however, in which a reasonable doubt exists let the patient have treatment, pending your decision, for Pott's disease.

## III. THE LUMBAR VERTEBRÆ.

When this region is affected the first sign to which the attention is directed is a lameness or a stiffness in one or the other limb. For a long while the patient will favor one side, at first almost imperceptibly, then there will be remissions apparently, and later marked flexion of the thigh. The physician when consulted does not get pains at the knee and does not get any tenderness at the hip-joint. He gets good flexion and good rotation and good abduction. He rarely thinks to explore the pelvis, and the patient is dismissed as suffering from rheumatism or "growing pains." By and by a tumor presents in the groin or in Scarpa's space, and even then the spinal lesion goes often unrecognized. Femoral hernia is diagnosed, hip disease with peculiar symptoms is thought of, idiopathic psoas abscess and simple cellulitis. The hand is occasionally passed up the spine, no deformity is felt and caries is excluded.

Let it be distinctly understood that a soft tumor in the groin or Scarpa's space especially, preceded by lameness extending over one or many weeks, unaccompanied by constitutional disturbance, hectic for instance, unassociated with stiffness at the hip joint, — smoothness of joint-surfaces, free flexion and free abduction, — and without a history of direct injury to groin or of intestinal symptoms, points to disease in the bodies of the last dorsal or some of the lumbar vertebrae. And this is as true of adults as of children. An idiopathic psoriasis is one of the rarest of diseases; an articular

ostitis of the hip will extend over many months and will make itself known long before abscess appears. Hernia can be recognized or excluded by an ordinarily careful examination.

To make a differential diagnosis between lumbar caries and perinephritis is frequently attended with considerable difficulty, especially if the perinephritis present an element of chronicity. As a rule, however, perinephritis in children is acute and is primary. In adults it is secondary to a pyonephrosis, and an examination of the urine will assist materially in arriving at a diagnosis. In Pott's disease there is always the element of chronicity. The spine in perinephritis is flexible, and one has no difficulty in thoroughly testing its functions unless, perhaps, the patient be naturally cross and unmanageable. The writer has often directed attention to the points in differential diagnosis in papers on perinephritis, and for a detailed account of the same he would refer the reader to the *American Journal of Obstetrics*, April, 1876, to the *American Journal of the Medical Sciences*, April, 1877, and to the *Chicago Medical Journal*, June, 1880.

The same difficulties arise in differentiating from iliac abscess or perityphlitis. It will be necessary simply to bear in mind these different affections and to remember that they occur with perhaps more frequency than text-books allow. In the *American Journal of the Medical Sciences* for January, 1881, I have reported six cases of perityphlitis as it occurs in children, and the points of resemblance are referred to at length.

It is not scientific, however, to wait for the tumor to appear above the surface. If flexion of the thigh occurs we should make palpation over the iliac region, and the presence of a tumor deep in the iliac fossa can be readily perceived. The general symptoms of bone disease will present here as in other regions.

A word now with reference to the occurrence of spinal caries in subjects suffering from caries in the neighborhood of other joints, more particularly the ankle and the knee joints. Time and again I have overlooked a spinal disease because my attention was devoted to a caries of the ankle or an articular osteitis of the knee. The lesson I have learned is to examine, if possible, the whole body in all cases of knee and ankle joint disease that present, especially if the patient present evidences of greatly impaired nutrition. My friend, Dr. T. E. Satterthwaite, called attention to this coincidence of diseases in his report to the Therapeutical Society on Suppurative Disease of the Ankle in Children and Young Adults, published in the *Medical Record*, August 21, 1880.

In conclusion, let me urge upon the profession the possibility of making a diagnosis of vertebral caries before the stage of deformity is reached, the duty of making the diagnosis, — a duty now all but imperative, — and the facility with which it can be done, irrespective of the region affected, if the physician cultivate a habit of submitting every case of disease in children, wherein the least element of chronicity enters, to a thorough physical examination.

— According to Dr. Carpenter, the average mortality from small-pox in the olden time, say from 1660 to 1780, was 1183 per million; but with the discovery of vaccination it fell to 2040; with the provision of public vaccination to 400; and under the compulsory vaccination system it has fallen to 276.

## HIGH-PRESSURE EDUCATION; ITS EFFECTS.

BY ROBERT T. EDEN, M. D.

IN private practice, that old but ever newly christened sister of debility and hysteria, successively appearing as "spinal irritation," "spinal" or "cerebral anæmia," or "nervous prostration," but now more familiarly known as neurasthenia, is only too familiar. In these wards, although the *clientele* of the hospital does not lie chiefly among the classes where this affection is most commonly developed, it is by no means rare. Here, as well as in private, it is far from being the exclusive property of the neurologist, for it has frequently claimed the attention of the surgeon, for some affection, real or supposed, of joint or "spine," and is almost certain to have received the assiduous cares of the gynæcologist before settling down into a well-marked condition of chronic invalidism.

The description of these cases in general terms, and with a just appreciation of all the varied symptoms which may attend them is unnecessary. The pains in back and head; the inability to read, to think, to act, and sometimes even to exist without increasing them; the general feeling of utter weariness, of loss of interest in all human affairs; the feeble and irregular circulation, leading to coldness, objective and subjective, of the extremities, and to many other abnormal sensations, perpetuated and magnified by an attention otherwise unoccupied, are familiar to all.

These patients are not necessarily hysterical or even "nervous," in the common acceptance of the word, but they have usually been well educated as to all the parts of their pelvic viscera which can possibly have an "itis" added to their names, are learned in pessaries, talk glibly of the "base of the brain," and know to the fraction of a milligramme just the dose of any drug, possibly the most feeble, which is required to produce an effect upon them.

The treatment of this affection is so largely moral and hygienic, depends so much upon the individuality of the patient and of her attendants, and has been the subject of so much literature, that I shall say nothing about it.

But my attention has been somewhat strongly directed to certain points in its ætiology, which have often been the subject of professional comment, but which will bear to be again discussed and insisted upon, since, in dealing with an affection, difficult and tedious in its treatment, which makes of so many who might be among the most useful members of society mere burdens to themselves and to the community, nothing can be of greater practical value than forcing upon the attention of responsible persons a realizing sense of its *avoidable* causes. These cases seem to originate under two almost diametrically opposite conditions, which may be briefly named, *underwork* and *overwork*. This apparent contradiction finds its parallel in the atrophy which may arise in cases having the appropriate diathesis, in those muscles which are most exposed to excessive exertion, or, on the other hand, in consequence of disuse or paralysis.

Invalids, who have become such because they have nothing better to do, have probably existed ever since there has been a class able to live without exertion, and willing to take advantage of the opportunity. The members of this class, who have felt no spontaneous impulse to work, and to whom external circumstances have furnished no definite object for labor of

any kind become the male valetudinarians and hypochondriacs, and furnish an important contingent to the array of female neurosthénics.

Among them we should find the "bed case" of the late Dr. Channing.

It is the second class, however, which appeals most strongly to our sympathies, while its existence robs the community of much more effective strength than the first.

For this class we may recognize modes of origin various in detail, but often coexisting or running into each other, and having this in common, that they involve not only mental occupation, but mental or nervous strain and tension, anxiety as well as work. It is not the steady road gait, be it fast or slow, as individual capabilities allow, that break down these patients, but the *racing*, either with each other or with those indefatigable antagonists, sickness and poverty.

Many groups of circumstances may furnish these conditions: household cares, nursing, friendly or professional, or, lastly, those which are the special subjects of this paper, over-schooling or over-study, either as scholar, teacher, or both.

The overwork is often a necessity. The future patient risks her nervous system in the cause of her friends or her family as distinctly and as honorably as the soldier risks his body for his country. It is for those who falter and fail in such a struggle that philanthropy most properly builds its hospitals and asylums; and for them, even if we consider them imprudent and misguided, we can feel only pity and sympathy.

But in others, breaking down under the absurd regimen of many of our schools, we have to regret the meagreness of results as well as the magnitude of the sacrifice, and share the doubts of the elder Mr. Welier in regard to matrimony.—"whether it is worth while going through so much to learn so little."

It would be difficult or impossible to show that preparation for and the practice of teaching are occupations peculiarly dangerous to nervous health. It is only under certain circumstances that they are so, but that these circumstances are of no infrequent occurrence seems a conclusion not at all difficult to draw from hospitals or from private practice.

The fact that out of nineteen patients in the Adams Nervine Asylum nine had been teachers, shows possibly only a coincidence, or, more probably, that teaching is the one vocation to which more educated women who are obliged to earn their own living resort than to any other.

That out of ten of these patients, whose cases may fairly be named "nervous exhaustion," seven had been teachers, certainly shows that teaching is *one* way of breaking down nervous strength. Illustration, if not proof, may be found in the subjoined histories, abridged chiefly from the records of this hospital or of the institution just named.

CASE I. Miss A., aged 34. A woman of rather large frame, and at present tolerably well nourished, has been an invalid for fourteen years. At seventeen she had typhoid fever, and has not been well since.

Two years later, when teaching, she noticed a gradually increasing sense of lassitude, lack of endurance, loss of appetite, pain in forehead, back, and neck, distress in the cardiac region, and vomiting.

She is subject to attacks of greater severity, during which she is confined to bed for weeks. At these

times there is a feeling of impending death; anguish, followed by extreme prostration.

She has improved somewhat within the last two years.

CASE II. Miss B., aged about 32, now tolerably plump, and of good color. At ten years old she was taken out of school sick; at fourteen had "slow fever"; at fifteen sent home from school, sick.

After this tried rising at four A. M. Studied sixteen hours a day, taking two hours for meals and six for sleep. She kept this up for two weeks, and broke down. Studied again, and became sick and delirious. About 1870, from too long walks, her legs gave out, and she could not walk.

Tried twice to teach. The last time she used to put her feet in mustard-water at night (to relieve cerebral congestion?) so that she might be able to go out the next day. Another sickness followed, with headache and "pressure."

Her present illness dates from 1874, from a short but severe mental strain (an essay on a somewhat difficult subject in one of the public schools in Boston), and is characterized chiefly by general weakness, and especially by inability to "use her head." She is improving slowly.

CASE III. Miss C. worked very hard as a teacher in a western city. Previously well, she broke down six years ago, was obliged to give up her profession, and has not been well since.

She has no symptoms but loss of strength.

CASE IV. Miss D., aged 23. A frail child, very ambitious and nervous. She studied until three years ago, when she graduated at a well-known female seminary.

She was troubled about her entrance examination, and soon after entering school her back began to trouble her. Has had attacks of dizziness, and two years ago had what was possibly a slight sunstroke.

She was, when last seen, a nervous invalid of the most pronounced type, emaciated, lying in a cold room with scanty clothing, and taking, to all appearances, so little food that it was difficult to understand how a normal body temperature could be approximated. She suffered intense pain in her right hand and arm.

Of her recent history I am ignorant.

CASE V. Miss E. suffered from dyspepsia, depression of spirits, emaciation, and "excruciating" pains.

Her physician says, "She was such a wreck that when she went to Philadelphia (to be under the care of Dr. Mitchell) I was glad to hear that she reached the place alive." She begins her own story: "1872, September. Teaching in N——, with some headache. Cold house and poor food." After this, though greatly improved, there were some years of ups and downs, with sleeplessness, nervousness, indigestion, and "local" (that is, supposed uterine) pains.

Is now fat, and very much better.

CASE VI. Miss F., of a nervous temperament, worked with great energy at teaching, and the care of her mother and sister (the previous case), until she gradually broke down and took to her bed.

While in the City Hospital she was in a condition of utter despondency, usually more or less concealed, but occasionally expressed in extravagant language, homesickness of the most extreme kind leading her to display a degree of cunning altogether foreign to her nature. Her notions as to her dyspeptic condition and the anatomical condition of her stomach amounted

almost to insane delusions, and rendered the task of properly feeding her a very difficult one.

She also is very greatly improved.

CASE VII. Miss G. In this case the breakdown, the headaches brought on by the least attempt at the mildest possible forms of so-called mental labor, the general debility, the torpidity of pathological as well as physiological processes, are, perhaps, less distinctly the consequence of school life than in some of the others, though diligent application, both as scholar and teacher, was supplemented by a tedious employment in the non-ventilated library of an eminent writer on hygiene. She improves slowly.

CASE VIII. Miss H., aged 32. There is a slight history of nervous tendency in the family of this patient. She was well until seventeen years of age, when there came three years of overwork. At twenty she was in Europe for four years of hard study. She used to go to bed at two, and get up at six for lessons. She then experienced flashes of light before her eyes, and a feeling of pressure upon the temples. A slight attack of diphtheria aggravated these symptoms.

In the spring of 1874 she began teaching in a high school in this neighborhood. She then suffered from intense headaches. She was very sleepy during vacations and when unoccupied, but afterward this condition was replaced by sleeplessness.

She has now been in bed for many months; is well nourished; and lately sleeps well, with a tolerable appetite. Her symptoms are chiefly the usual pain in head and spine, general hyperæsthesia, and constipation. She improves, and, I have lately heard, walks a little.

CASES IX. to XIII. Misses I., J., K., L., and Mrs. M., are all nervous invalids; all inmates of the Adams Nervine Asylum, and have all been teachers; though the connection between their present condition and their occupation is less clear than in most of the cases just cited.

The case of one of them obtained considerable notoriety through the daily papers as a cure by prayer and the laying on of hands.

As to the pathology of these cases it is difficult to speak, except in negations or metaphors. Morbid anatomy they have none. Frequently emaciated or anæmic; often enough, at least, to justify the treatment so widely known by the name of the eminent specialist of Philadelphia, yet all these cases do not depend upon want of fat or blood as the essential condition. Fattening may improve, but does not always cure. The hypothesis of a local anæmia of brain or cord is, in the first place, unsupported by facts; and, secondly, insufficient to account for the symptoms; and we are obliged to fall back on various ostensible explanations, which, after all, amount to but little more than stating, in various verbal forms, that the nervous centres, and especially the higher ones, fail to do their duty without rapid exhaustion, and give rise to more or less abnormal manifestations.

We have not as yet found either larger or smaller ganglion cells in these cases than in the normal brain; no fatty or calcareous or hyaloid degeneration; no interstitial hyperplasia has been shown. It is far from demonstrated that they are not supplied with blood as abundantly and of as good quality as is to be found in many other diseases attended with a much greater degree of organic mischief, and yet entirely free from the strange set of phenomena here noticed. But notwithstanding all this these cells will not work.

Why? I doubt if we know until the laws of nervous force are much better understood than now; until, for instance, we can explain exactly in what consists the so-called "inhibitory" action; or can tell why one degree of irritation should simply cause increased action and a higher degree absolute paralysis.

This latter doctrine of stimulation and over-stimulation, so necessary, so clearly, and so demonstrably illustrated in the physiology of nerves whose functions are made obvious by muscular contractions, as the vaso-motor or motor nerves, has undoubtedly much to do in the explanation of cerebral-spinal debility. But an analogy does not give us a satisfactory answer to our questions.

The various agencies which may make so long-continued and serious a draft upon the productiveness of the nerve-cells that the supply of force is not for years again equal to the demand, or the kinds and amount of shock or strain which permanently paralyze them, have been already mentioned. The one which I have made the subject of this paper is among the most important, not only because one of the most frequent, but because avoidable; and because so much of our school system seems almost expressly designed for the manufacture of nervous invalids from material only too easily worked, and too abundant, in the form both of scholars and teachers.

Offensive though it may be to those who consider any intimation of mental or moral difference in the sexes as almost an insult to their own, the fact remains that the cases of nervous debility from this cause are very much more common in women than in men; and although, of course, the much larger number of women employed as teachers accounts for a portion of this difference in those whose breakdown comes a few years later, and is correspondingly more complete, yet the scope of education for the two sexes is now so nearly the same, and certainly no more exacting for one than the other, that we must suppose, for the earlier cases at least, either a relatively less power of resistance in the female, or a very different way of attacking the task.

I think we may find here a sort of paradox, and say that the breakdown of many women is owing to their superior powers of endurance; that is, of endurance for a time, under nervous excitement.

A boy of moderate ability, even with some ambition, and anxious to do well, is apt soon to realize his true position, and content himself with such moderate scholastic honors as are easily within his reach, and to get his sleep and recreation even at the expense of class standing,—a philosophical procedure, in carrying out which, however, he has this immense advantage over his sister, that he realizes at a very early age that many avenues are open for him toward success in life, and that in only a few of these is high scholarship of any advantage whatever, and in some, perhaps, even a drawback.

What we are to name that impelling force which drives on the girl to pursue her studies, and sometimes, if trying to be prudent in matters of hygiene, her sports, with a "tireless sort of energy," is not easy to say. It seems to be a compound of conscience, ambition, and a desire to please, in varying proportions with a peculiar feminine sort of obstinacy which, in a better cause, and reasonably directed, would demand admiration rather than pity.

The more sensibly conducted the studies, and the

better the physical training, the better are the results. The studies of the school girl may lead to those of the woman learning a profession, or pass into those of the "higher education." In other cases all further trouble is averted by the readiness with which all study is given up forever when the "education is completed."

The exhaustion will probably come sooner or later, but is not so likely at this stage to be permanent or complete.

For the full development of a case of neurasthenia something more than even a first-class female conscience is usually necessary; though this, if hypersensitized, may do the whole work. An outside pressure is required, and this may come from domestic or friendly cares; but the most efficient form in which it can be applied is that to which the teacher may be subjected, and under such a pressure a very large proportion of the overworked and ambitious scholars come.

Regular and legitimate mental labor is, like any other reasonable exercise, conducive to the well-being of the organ employed, and there is no reason why teaching should not, like other intellectual occupations, conduce to health and longevity. So it would often appear to do, for, in the first place, education has not always been, and is not always, conducted with the intensity demanded in our public schools. It may be, and sometimes is, really education,—a drawing out and developing, and not a cramming in. Or, secondly, the cares of the teacher may fall upon those happy dispositions which shed their troubles as a duck does the water, and remain indifferent to expected praise or blame.

Those, however, who control these matters on a large scale apparently forget that the quantity of information which the scholar's mind can usefully hold does not depend upon the maximum amount which the teacher is capable of stowing away in a given time, but upon its original capacity.

Into a number of knowledge-boxes, all of varying size and shape, a certain, and usually large, amount of information on a dozen different subjects has to be packed. Fortunately many are leaky. The knowledge runs out nearly as fast as it runs in, but the box remains whole.

Those which cannot get rid of it so easily are the ones which are cracked.

A girl preparing to teach, or, what is perhaps even a more unfortunate case, an old-fashioned teacher being remodeled, has to learn (!) half-a-dozen arts and sciences, to a limited department of any one of which a man devotes his lifetime.

The highly important question of the relation of female education to the physical peculiarities of the sex I have purposely avoided, although by no means unconnected with my subject.

I cannot forbear, however, quoting the following passage from an eminent authority, as showing that nerve centres alone do not bear the whole strain of high-pressure education:—

"On looking over my case-books I have been surprised to find the same statements repeated again and again, namely, that the sufferer had taken the highest honors at some noted female school or college, and gave no tangible signs of weakness until reaction took place after her return home."—"I hold that it is not practicable to educate a girl by the same method found

best fitted for a boy without serious consequences afterward."<sup>1</sup>

If, as I believe, our system of education is responsible both by omission and commission, for an important proportion of the chronic female invalids, the remedies are easily to be seen, even if not so easily obtained. They are; moderate and carefully regulated bodily exercise; less studying for prizes and more for knowledge; lesser demands upon teachers; fewer scholars; and, perhaps most important of all, lucrative employments beside teaching which shall be considered respectable for women.

## RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M. D.

THE proceedings of the Anatomical Section of the International Medical Congress held last summer, in London, contain a great deal that is valuable which we should wish to present to the readers of the JOURNAL. Unfortunately, however, we have not yet had access to the volume in which they are published, and though some of the papers have appeared elsewhere we know nothing more of others than can be gathered from abstracts far too short to be satisfactory. We miss, also, the instruction that would be gained from full reports of the discussions that followed the various papers. For instance, Professor Struthers read a paper on the supracondyloid process of the humerus, which appears to have elicited a very interesting discussion, but we have met with no account of the paper sufficiently exact to be worth reproducing.

## THE CAUSES OF THE FORM OF BONES.

Professor Lesshaft, of St. Petersburg, read a paper on this subject which deserves a fuller report than the abstract allows us to give of it. He made a series of experiments with Dr. Popoff which led him to the following conclusions:—

"(1.) The development of every part of a bone is in relation with the activity of its neighboring muscles. When activity is great the bones are strong; but when feeble, the bones become thinner, weaker, more slender, and relatively longer.

"(2.) The form of the bones varies when the resistance of the neighboring organs is lessened; in such cases the bone grows thicker towards the part which offers least resistance.

"(3.) The form of the bones depends upon the greater or lesser amount of pressure by exterior organs; development is diminished whenever outside pressure increases; and if pressure be only directed on one side the bone accordingly alters its shape and curves.

"(4.) The aponeuroses, which are under direct muscular influence, also exert a lateral pressure, which is lessened by section of the aponeurosis. This has the same effect on the form of the bones as removal of portions of the muscles themselves.

"(5.) The bones are active organs as far as their structure is concerned, serving as a basis and support to adjacent organs; but they are passive in relation to those organs. This relation depends mainly on the sources of their common nutrition, which increases as

<sup>1</sup> Emmett, Principles and Practice of Gynecology, 1879.

the pressure of adjacent parts diminishes, and as the action of neighboring muscles is developed."

#### THE POSITION OF THE STOMACH.

Any one who for the first time consults any English anatomical text-book will conclude from the figure of the stomach that meets his eye that this organ lies in the main transversely in the abdomen with the lesser curvature above and the greater below. Indeed, this is essentially the description of its position that is given in the eighth edition of Quain. Yet it is nearly twenty years since Luschka declared that the lesser curvature was vertical in the greater part of its extent, and as far as the writer is aware, though this view has been very generally ignored, especially by English anatomists, it has never till last summer been contradicted.

Professor Lesshaft read another paper before the Section of Anatomy at the International Medical Congress, On the Situation of the Stomach based on the study of 1200 subjects. His views on the position of the stomach are those of Luschka, but in addition, he gives theories as to the development of the peculiar shape of the organ. It is perhaps best to quote from the abstract of Lesshaft's paper:—

"(1.) The stomach is placed vertically in the abdominal cavity, so that its fundus touches the diaphragm; its pyloric extremity is to the right; the lesser curvature is also to the right, with the upper part slightly inclined downwards; the great curvature is to the left.

"(2.) The stomach is in the left hypochondriac region, and exclusively in the gastric region proper. The pylorus corresponds to a line drawn vertically downwards from the right border of the sternum.

"(3.) The stomach, in consequence of its intimate relation with the neighboring organs, cannot dilate by the displacement of one of its parts (the great curvature, for example); it can only become equally distended in all its parts in proportion to the accumulation of its contents."

We must admit that this proposition seems to us open to question, at least when the stomach is only partly full; perhaps, however, Lesshaft refers to its distention beyond its perfectly normal size.

"(4.) The muscular coat of the stomach is made up of longitudinal, transverse, and oblique fibres. The longitudinal fibres are directed from the fundus towards the pylorus, and the circular fibres become thicker as they approach the latter; they are especially noticeable in the neighborhood of the pylorus, where they form a true sphincter. It follows that the food-stuffs move in relation with the walls toward the pylorus, and this permits of a very advantageous admixture with the gastric juice. Then the contents return through the middle of the stomach towards the fundus, as there is here less resistance on account of its larger size.

"(5.) The peripheral movement of the contents of the stomach from the fundus towards the pylorus, and the central movement in the opposite direction, can only take place in consequence of the special shape of the stomach. The absence of the fundus in the newborn child and its after development can be accounted for by taking into consideration the influence of the returning middle column of digesting food upon the walls of the stomach. With regard to the lengthened

stay of the food in the stomach, and the slowness of its after passage through the small intestines, it can be explained partly by the shape of the stomach, and partly by the disposition of its muscular fibres. . . .

"(7.) A large stomach, accustomed to a generous food-supply, always retains its vertical position, and it is only the pyloric extremity which is directed upwards and to the right."

From the very meagre report of the discussion that has reached us we learn that Mr. Holden was unable to agree with Professor Lesshaft, that Professor Allen Thompson thought that the stomach was situated almost transversely, and that several other anatomists were of the same opinion. This divergence is most surprising, as the matter, one would think, could be easily settled. The difficulty, perhaps, is due to the fact that the edge which forms the greater curvature describes in its course from the cardia to the pylorus about three quarters of a closed curve, and that, looked at under varying circumstances, the long axis of the stomach may appear sometimes more or less vertical, sometimes more or less horizontal. The two following points, however, establish to our mind the correctness of Luschka's and Lesshaft's views: the greater end-de-sac points upward and the lesser curvature is in the main vertical.

#### THE POSITION OF THE OVARIES.

Professor His<sup>2</sup> contributes a new paper to the rapidly increasing literature of this vexed question. He holds, in the main, to his theory that they lie with one side resting against the wall of the true pelvis and that the long axis is vertical, a view which appears to have gained ground since its publication in 1878. He has since very carefully examined the position of these organs in three suicides aged respectively fifteen, sixteen, and twenty years, and finds, as indeed might have been expected, that if the fundus of the uterus is on one side of the median line the ovary of the opposite side is drawn downwards and into an oblique position. It is evident that after this position has once been reached the weight of the viscera will tend to press the ovary more and more from its normal position. Summing up the results of all his observations His gives the following as the normal or primary position of the ovary in the young adult female. The organ lies with its side against the wall of the pelvis, the free border being behind and the attached end below. The Fallopian tube is looped over the ovary, rising along the front and falling behind it. The fimbriae then turn back and spread over the summit of the ovary.

It should be remembered that with advancing years and after repeated pregnancies the situation of the ovary must become more and more uncertain.

#### RESEARCHES ON THE VEINS.

Professor Friedrich,<sup>3</sup> of Heidelberg, who is engaged on an elaborate paper on a series of clinical questions which have reference to normal and pathological murmurs in veins, has published a preliminary paper on the occurrence of valves in the femoral and some of the abdominal veins. He has examined 185 subjects, or 370 extremities. He found that in the upper five cms. of the femoral vein valves were present on both

<sup>2</sup> Archiv für Anatomie und Entwicklungsgeschichte, 1881, heft 4 and 5.

<sup>3</sup> Morphologisches Jahrbuch, Band vii., heft 2, 1881.

<sup>1</sup> We regret that we have seen only an abstract of this paper.

sides in 137 subjects, and in 26 on one side only; in other words, in 300 of the 370 legs. From these, however, we must subtract 28 legs in which the veins were insufficient, either from want of development or from pathological processes. This leaves 272 (74 per cent.) extremities in which there were good valves in the femoral vein within five cms. of Poupard's ligament. In no single case were valves wanting at the opening of the profunda into the femoral vein, and only twice were they rudimentary or obviously inadequate. It is generally taught that no valves are found in the continuation of the femoral vein inside of the abdomen, and the most valuable point in the paper before us is the refutation of this axiom as a universal rule. Friedreich found valves in the external iliac veins of both sides of 41 subjects, and on side in 48. That is to say, in more than 35 per cent. of the extremities. They were found more frequently in the upper than in the lower half of the vein. It is especially noteworthy that valves occurred in the external iliac vein in but a few of the cases in which they were wanting in the upper part of the femoral, and thus their presence cannot be explained by saying that they are merely the femoral valves somewhat displaced. More than one third, however, of these valves in the external iliac veins were found insufficient.

Valves were found in the common iliac vein five times, two of them being symmetrically placed in the same subject. The author has never found any in the inferior cava.

Dr. E. Henry Fenwick read a paper on the subcutaneous veins of the trunk before the Anatomical Section of the International Congress. We regret that we have seen only a brief abstract, from which we quote. "His method of investigation was first to dissect bit by bit the venous branches in an uninjected subject, and make an accurate drawing of them. The veins were next injected in another subject and dissected, the position and direction of the valves being ascertained. After treating several subjects in this way, it was found, among other results, that the vein-trunks proceed from the venous net-works on the anterior surface to the femoral, axillary, and subclavian veins, and that Braune's fascial pump-like action, which these large spaces exert upon them, is materially assisted by valves appropriately directed and placed at the mouths of these vein-trunks. The long vein-trunks which connect the femoral with the axillary vein of either side have, at and toward their mouths, powerful valves so directed as to prevent the passage of blood from the extremities into the abdominal and thoracic wall systems. The superficial are connected with the deep epigastric veins, and are possessed of valves allowing the blood to pass from the former to the latter, but opposing its return. The deep epigastric with the internal mammary vein forms a system similar to that found in the superficial epigastric vein. The intercostal veins connecting the azygos with the internal mammary vein have precisely the same valvular arrangement."

There may not be very much really new in Dr. Fenwick's paper (of which, by the way, we have not given the full abstract), but it deserves mention as an instance of good work in a neglected field. It is evident that knowledge of practical value can be gained from a study of the course of the venous blood in different regions, and it is to be hoped that similar investigations will be continued.

#### ARRANGEMENT AND VARIATIONS OF THE CEREBRAL SINUSES.

Mr. J. F. Knott<sup>1</sup> has studied the arrangement and the variations of the cerebral sinuses, and publishes his results in a paper of considerable value. A work of this kind cannot be satisfactorily condensed into small compass, so we will notice a few points only. Mr. Knott finds that the torcular Herophili usually inclines to one side. It was mesial only eight times in forty-four cases; it inclined to the right twenty-seven times, and to the left nine times. He states that the right lateral sinus is usually the larger, but we are surprised that he describes it as being only four times the direct continuation of the superior longitudinal. Possibly he means that these were the only cases in which the latter sinus turned wholly to that side without any communication with the other, but he seems to overlook the fact (as we believe it to be) that though this sinus communicates at the torcular with both lateral ones, yet only one can, as a rule, be called its continuation. He found the superior longitudinal sinus precisely in the middle of nine calvaria out of thirty-eight. He found it bifurcating in two cases a little behind the coronal suture, the two branches renniting an inch and a half further back. For reasons that may be apparent presently we will quote from Mr. Knott's description of the straight sinus: "This vessel, which is formed by the confluence of the inferior longitudinal sinus with the vena magna Galeni, passes backward and downward to join the torcular Herophili, or (what oftener happens) it may turn a little to one side to pass into one of the lateral sinuses. 'It opens, for the most part, by an oval mouth, formed by strong pillars of fibres, into the left lateral sinus, rather than directly in the middle of the communication of the three great sinuses.' Such is the description of its termination given by Sir Charles Bell, and it is entirely in accordance with my experience. In twenty-six cases out of forty-four it opened into the left lateral sinus, the terminal orifice answering exactly to the description above quoted. In six cases the deviation was to the right, while it ended medially in twelve instances."

We are surprised that Mr. Knott did not make a very evident deduction from such accurate observations, which has, indeed, been made by Rüdinger, but has not received the attention it deserves, to wit, that normally the superior longitudinal sinus turns to one side (generally the right) and the straight one to the other. They communicate, as a rule, at the torcular, but still the latter is not usually formed by a splitting of the superior longitudinal in the way commonly supposed.

—The annual banquet of the Union of the Titans, the prime requisite for membership in which is a stature of at least six feet and two inches, was recently held at Delmonico's, New York city, and the medical profession was represented by quite a number of its "big men" on that festive occasion. Among the toasts of the evening were "Prometheus," which was responded to by Dr. William A. Hammond, and "Apollo as an Æstheté," to which Dr. A. E. MacDonald responded.

## Hospital Practice and Clinical Memoranda.

### A CASE OF OPTICO-CILIARY NEUROTOMY. FAILURE. ENUCLEATION.

BY DR. EDMOND LANDOLT, PARIS.

TRANSLATED BY HASKET DERBY, M. D.

[THE question as to whether the division of the optic nerve might not prevent an injured eye from affecting its fellow sympathetically, and thus render unnecessary its removal, has been seriously entertained by eminent surgeons. The weight of evidence, however, is gradually accumulating against the belief that enucleation may thus be superseded. The following case, recently published by my friend, Dr. Landolt, goes to confirm this statement. H. D.]

Jacquin, sixty-seven years old, came to my clinique April 15, 1880. His left eye had long been lost, and he now requested an examination of the right, inasmuch as it was the seat of pain, and its vision diminishing. I found: left, absolute amaurosis; right, myopia 20 dioptries, acuteness of vision 0.05.

**History.** Twenty-two years ago the patient was profoundly affected by the death of his brother, who expired in his arms. He soon suffered from hemorrhages from both mouth and nose, and from a stomachic derangement that lasted five years. During all this time he could take no meal that was not immediately followed by vomiting. It was about then that, returning from a visit to one of his relations, he had a fall on the stairs of the Paris railway station. On being raised up he declared that he could not see. "They have put out the gas," he said. Severe pain came on in the left eye; for six weeks he was attended by an oculist, without any return of vision in either eye. Another oculist, who was consulted, stated the condition to be: "Left, numerous hemorrhages, separation of the retina; right, impending separation." For three weeks he had derivative treatment, cupping, etc. Vision returned in the right eye. Great care was taken, the patient remained in a dark room, and refrained from work. For a long time, some fifteen years, his condition was tolerably satisfactory. He used his right eye, but never saw again with his left. Suddenly a fresh hemorrhage occurred in the right eye, while he was at work; derivative treatment was again used, and was once more followed by a return of vision. There followed now another cessation of disturbance until 1880, the time of the patient's coming to me. This time the left eye became the seat of exquisite pain, the vision of the right fell to 0.05, sympathetic irritation became evident. In the left eye there was deep circum-corneal injection, the aqueous was turbid, the iris discolored, and there were numerous synechiae. No reflex could be had from the fundus, the tension was increased, and the eye tender on pressure, especially in the ciliary region. In the right eye there was found an extensive inflammatory choroidal atrophy, a posterior staphyloma, circular in shape, and floating opacities of the vitreous. Visual field contracted.

I proposed the enucleation of the right eye, but the patient hesitated at this, and finally refused. Having probably heard something about neurotomy, he finally requested this operation, and declared he would go no farther.

This I performed, under chloroform, April 20th. I

passed a thread through the external rectus, and divided the muscle in front of the thread, then, seizing the stump with forceps, I introduced a pair of curved scissors, and divided the optic nerve. I then revolved the eyeball until its posterior pole presented at the palpebral aperture, excised the portion of the optic nerve still adherent to the globe, and freely incised the tissues round about the nerve. Bleeding was free; I replaced the eye, and reunited the muscle to its tendon. A compressive bandage was applied. There was but little inflammatory reaction, and sensitiveness disappeared.

April 24th the suture came away, pain ceased, and the corneal sensitiveness returned.

April 29th. Corneal haziness, ciliary pain.

May 10th. Corneal ulceration.

May 28th. I again measured the right field of vision, and found it still decidedly contracted (85° out, 45° in).

June 18th. Tension diminished, the keratitis has disappeared. Sensitiveness at the corneal centre, but not yet at its periphery.

On the 10th of June I again took the visual field, and found it even more contracted, extending but 60° out, and 42° in. The acuteness of vision kept pace with this diminution. The operation had evidently failed to arrest the progress of the disease, and I renewed my original proposal to remove the left eye.

The patient did not return till October 10th. The left cornea had become anæsthetic over its entire surface, the eye was phthisical. Operation again proposed, and again refused. January 31, 1881, I found the myopia to be 20 dioptries, the patient counting fingers at 2.5 metres. Posterior synechia, aqueous cloudy, iris yellowish. The eye was excessively sensitive at its lower part, beneath the cornea. A corresponding point of sensitiveness, slightly to the inside of this, was found in the left eye. I strongly represented the necessity of enucleation, telling the patient his sight would steadily diminish until total blindness ensued. The contraction of the visual field remained the same.

February 1st he returned, his vision was still falling off, the optic nerve was much congested.

March 2d. There had been for several days pain in the right side of the head; fingers could be counted in two metres. The patient, however, was no longer able to go about alone, and was hence made to realize the more forcibly the failure of his sight. There was the same exaggerated local sensitiveness in each eye. The right eye looked dull, pupil contracted, anterior chamber cloudy. Enucleation was at last agreed to, and performed the same day. Under chloroform it was done without difficulty. The patient slept the first night, pain having completely vanished. The right eye already looked better, although the pupil failed to respond to atropine. The patient left the clinique March 7th, finding his way about much better than before.

Optico-ciliary neurotomy has done good, a fact on which its friends have not failed to insist, but, as is the case with every new operation, it has been the old story over again. The inventor gets nothing but good results, his followers publish no others, a false sense of shame causing them, perhaps, to hold their peace, when their efforts have not been crowned with success. Such are the difficulties that beset a proper estimation of the value of a new operation. The case I here publish seems to me to afford, in itself alone, ample ground for the utter rejection of optico-ciliary neurotomy where sympathetic ophthalmia is dreaded. And I

hope my colleagues will publish broadcast their failures in order that light may be shed on the danger incurred by a patient who squanders precious time on an operation, the final result of which is not at once felt, instead of submitting to enucleation.

# REPORT ON MALARIAL FEVER IN THE NEIGHBORHOOD OF PROVIDENCE, R. I.<sup>1</sup>

BY HOMER BATCHELDER, M. D.

On closing my first communication on the subject of Malarial Fever I had supposed that the disease had had its run and I should have no further occasion to speak of or treat any more cases of malarial disease. The number of attacks through the latter half of October had dwindled down to five or six cases, and none during the last week; I felt well assured that I should not be called upon to treat new cases. But on the fifth day of November I was summoned to a young man's bedside, who appeared to be very sick. After learning the previous history of the patient, with a careful examination and analysis of all the symptoms, I was quite forcibly impressed with the fact that this was still a case evidently suffering from the effects of malarial poison, yet differing in many essential features from the *intermittent type* of fever that I had been called upon to attend and treat during the preceding four months.

**CASE I.** This young man was nineteen years of age; had grown to manhood very rapidly; was robust and healthy. He had during his childhood and youth scarlatina, measles, and whooping-cough. When I first saw him his pulse did not beat over sixty-five times a minute, and was small and irregular. His tongue was not really coated, but exhibited a sort of erectile appearance of the villous coat, representing in color a bluish gray,—not very unlike that of the serous membranes lining the cavities.

He had been slightly ailing for two days or more, though I could not learn that he had had any real ague chill; but in the morning previous to my visit at four p. m. he had experienced a passing sensation of chilliness, with alternate flashes of heat. The most prominent symptom, as well as the one most urgent, was an almost intolerable oppression at and through the gastro-hepatic region. The slight chilly sensation was in no sense like the *ague chills* which are premonitory, almost invariably, of intermittent malarial fever; while here, as in true ague, his chilliness was subjective, as his temperature already indicated 2° F. above the natural standard. He now began to suffer quite severely from headache. His stomach appeared to be hyperæmic and his bowels distended with gas. Urine about the color of strong coffee. I diagnosed the case as one of malaria, but varying a good deal in its general developments from those I had previously attended.

After prescribing some palliative treatment I left, with the understanding that I would see him again in six or eight hours. At the end of eight hours I hastened to his bedside again. I now found his pulse much accelerated, 115 strokes the minute, not throbbing, irregular, but rather compressible. I found that the hot stage had steadily increased from the time of my first call, and for three or four hours he had been very much nauseated, and had vomited considerably with

little if any relief. I found him also with a flushed countenance and suffused eyes; and now he complained of a raging headache, with a distressingly painful sensation through his limbs, loins, and back. The surface of the body was much redder; he was constantly tossing and turning in bed.

These symptoms gradually waxed stronger during a period of nine hours, at which time they began to abate, the heat of the skin to subside, and the pain of the head was partially relieved. The stomach became more quiescent, and the patient found comparative rest.

Although some of the features of this long train of symptoms seemed very much to resemble those I had often witnessed in intermittent paroxysmal fever, yet the differences were sufficiently marked.

Three days later I was called to visit another case which exhibited the same phenomena, only the symptoms were less severe than those witnessed in the first case. At this time I began to believe that the symptoms as observed in these two cases in most of their features represented remittent malarial fever. The disease has held this remittent type, and continued through the months of November and December with four or five mild cases during the first half of January of the current year.

Since the thirty-first day of October I have attended forty-six cases of remittent fever, twenty-three in November, eighteen in December, and five in this month, January.

I have been thus particular in narrating the general symptoms as accurately observed in the first case, because the symptoms as described in that case predominated with slight modifications in every subsequent case.

There was no fatal case, or rather no one died here in this community from the effects of remittent fever. But there was a man, I should judge between fifty and sixty years of age, who had been a resident of the place three years or more, but had no relations here, a shoemaker by trade, who began to show signs of malarial disease early in October. The disease assumed a chronic form; his case grew more grave, and I advised him to go to his friends in Mendon, Mass. He died just three weeks after he left, but I know nothing of his history after he left Arlington.

The ages of the forty-six cases of remittent fever were about as stated below:—

|   |    |
|---|----|
| The number under ten years . . . . .                  | 13 |
| The number between ten and twenty years . . . . .     | 7  |
| The number between twenty and thirty years . . . . .  | 8  |
| The number between thirty and forty years . . . . .   | 6  |
| The number between forty and fifty years . . . . .    | 4  |
| The number between fifty and sixty years . . . . .    | 4  |
| The number between sixty and seventy years . . . . .  | 3  |
| The number between seventy and eighty years . . . . . | 1  |
| Making a total of . . . . .                           | 46 |

A larger proportion of the above cases suffered from the fever in a protracted form than of those who had the intermittent type. Neither did the above patients rally from its prostrating results and vital constitutional disturbances in the same period of time as those mentioned in my former paper, nor was their restoration so complete.

**Enlarged Spleen.**—There were five cases in which the spleen became greatly enlarged as a direct result from intermittent malarial fever; and three cases after severe attacks of remittent fever. But they were all

<sup>1</sup> Continued from page 538.

cases where the disease had in the first stages failed to respond to the administration of quinine, the symptoms continuing persistent, while finally the disease in some respects changed its more general features and lapsed into a protracted secondary fever. These cases will be brought to the notice of the reader when the subject of treatment is discussed.

I am more or less convinced that where malarial disease prevails epidemically, and is at the time the primarily prevailing disease, no other of the zymotic diseases will find a foothold in the family or neighborhood where it prevails to any extent. But, on the other hand, where any of the zymotic diseases are prevailing in advance it makes no difference with malaria; other diseases form no barrier to its insidious occupancy.

These conclusions I first formed in the earlier part of the late War of the Rebellion, and they were afterwards strengthened by my own observations concerning the working of the disease among our soldiers while they sojourned in the South. Those who contracted malarial disease primarily very seldom suffered much from dysentery or diarrhoea, and scarcely ever from typhoid fever as a secondary complication. But neither typhoid fever, diarrhoea, or dysentery exhibited the slightest prophylactic influence in preventing an attack of malaria.

During the summer and autumn months of 1881 intermittent and remittent fever was the only disease prevailing to any extent throughout the circle of my practice. There has been no genuine typhoid fever, no dysentery, a few cases of cholera infantum, and perhaps five or six cases of sporadic but mild scarlatina. But none of these patients were of the families who suffered with malaria.

The territory wherein malaria in its different forms has mostly prevailed in my neighborhood seems to be confined within the limits of an oblong circle, of which the greatest diameter would not exceed two miles and the shortest not over one mile and a half. I do not intend to be understood as saying that there did not occur occasionally a scattering case outside of this imaginary circle. I attended five or six patients outside, three or four of whom resided three miles and a half away; but they had till within two or three months resided within the circle. I have also learned that other physicians in and out of the city of Providence attended some cases which were not within the territory where it generally prevailed. About one third of the northeastern part of this circle is situated in the southwest part of the city limits, while the remaining two thirds is that portion of the town of Cranston contiguous to the other third on the city line. The population is about four thousand, and the number of persons who have had an attack of malaria is not much less, if any, than three hundred and fifty.

The superficies of the greater portion of this location is alluvial and sandy, resting on a substratum of dark aluminous soil as a base, commingled with a sort of chip stone, forming a pan or bottom stratum, quite impervious to water.

There are and have been for many years within the eastern half of this malarial territory four ponds. The larger pond of the four is the one that is known by its Indian name as "Marshpang." It has a sandy or pebbly bottom. The shores are bold, and there are no marshy flats or shoals, no jungle or other obnoxious growths around it. It is well known to be one of the

purest sheets of water in the State, and every outward fact most certainly goes to disprove the theory advanced by some that this pond has been one of the probable sources of malaria.

Within a half mile west and north there are three other small ponds. These ponds have undergone no material change during the lifetime of any person now living. There is no jungle, and they are mostly surrounded by a marginal growth of thrifty wood; and during the summer months the atmosphere is made delightful by the fragrance from the abundant growth of the white pond-lily.

There is one other possible cause, which some persons have assigned, and they are still persistent in their belief that from this source sprang much, if not all, of the miasm that has infected this community with malarial fever.

There have been carted from the city of Providence, by those licensed to do so, about two hundred tubs, as a daily average, of twenty-five gallons each, of refuse collected from privies and cesspools, together with other noxious deposits, through Cranston Street to a point just outside the city line and emptied, either in heaps or broadcast upon the surface of a large proportion of the vacant or unoccupied lands located in the district in which malarial fever has been so prevalent. This business has been quite vigorously carried on for two seasons past, this very district being made a sort of depot wherein to deposit a large proportion of the foul excrementitious and noxious accumulations of the cesspools, together with other accumulated filth from the city, until the land in many localities became so saturated that the foul odor exhaled from the surface in some conditions of the atmosphere was intolerable. It is but just to state that this work was, on complaint, suppressed some time during the fall of 1881. Now that diphtheria, typhoid fever, dysentery, and perhaps some other zymotic diseases, may derive their origin from sources of this kind there remains scarcely a doubt. But whether the miasm which evidently results from these noxious combinations after exposure to atmospheric influences is identical with that which begets "genuine malarial fever" there seems to exist well-authenticated doubts.

I will allude briefly to one other cause which some of the most eminent writers upon the subject have classed with the more legitimate and fruitful sources of genuine malarial fever. "Malaria is produced or generated in hard rocks, such as granite and trap, in a disintegrating state, which are highly absorbent of water and often become permeated by a fungus."

There is within a half a mile of the city line a very extensive stone quarry. The composition of the rocky formation consists of what might be termed granite-gneiss. The position of these rocky strata is not a horizontal one but semi-upright, with open fissures packed with black, heavy, earthy deposits, the whole resting on a watery base. This quarry ranges in a direction from northeast to southwest, and presents a front facing the southeast for the distance of about one hundred rods, with an elevation almost perpendicular, averaging from fifty to seventy-five feet in height. This quarry is constantly being worked by the process of blasting and otherwise, as it affords the most abundant supply of material used in the construction of cellar-walls in Providence to be found anywhere in this vicinity.

There have been more cases of malarial disease

within half a mile of this quarry than have occurred in any other section of the same size within the sphere of its operations, although the population is more sparse than in either of the other localities where the disease seemed to prevail. On the other hand, however, this quarry has now been operated for fifty or more years, and it is not known that there has ever occurred an individual case of primary malarial fever antecedent to its appearance in the autumn of 1880.

## Reports of Societies.

### PROCEEDINGS OF THE MONTHLY PHARMACEUTICAL MEETING OF THE MASSACHUSETTS COLLEGE OF PHARMACY.

B. F. DAVENPORT, M. D., REGISTRAR.

At the regular meeting of February 13, 1882, SILAS S. BRADFORD, PH. G., read a paper upon

#### COTTON-SEED OIL,

describing the methods of manufacture and bleaching. He recommended its substitution for olive oil in certain pharmaceutical preparations. The paper was fully illustrated by the exhibition of specimens of the various grades of the oil, and of the official preparations made therewith instead of with olive oil. He also mentioned the increased use of the oil in the South in domestic cooking in the stead of lard.

MR. F. A. DAVIDSON mentioned having met with specimens of the oil adulterated with lard oil.

PROFESSOR MARKOE spoke of its extensive exportation and the reimportation under the name of olive oil.

MR. W. A. CHAPIN had difficulty with lin. ammoniac made with this oil from its becoming too thick to be poured from the bottle.

WILLIAM W. BARTLET, PH. G., read a paper upon

#### PEPSIN, PREPARATIONS AND METHODS OF ASSAY.

He recommends a modification of Prof. E. Schaffer's method of manufacture as published in 1872. He macerates hog-stomachs freed from all possible mucus and muscular tissues in a very dilute solution of hydrochloric acid, this solution by a series of settlings and strainings he gets into a clear condition, and then precipitates out the pepsin by the addition of sufficient powdered table salt instead of using a saturated solution. He thus avoids the great increased volume of the fluid, which would still hold much of the pepsin in solution thereby decreasing the amount obtained. This pepsin precipitation is skimmed off, pressed, and dried and, after being mixed with a weighed amount of sugar of milk this stronger saccharated pepsin is assayed and then mixed with as much more milk sugar as is necessary to bring it to the standard strength. This strength is that ten grains dissolved in one fluid ounce of distilled water acidulated with six drops of hydrochloric acid, shall in six hours, with constant agitation at the temperature of 100° F., dissolve just 200 out of the 300 grains of finely comminuted egg albumen which has been added. This albumen is prepared by boiling an egg for five minutes, chopping finely the white, and then passing it through a No. 60 sieve. Any variation in any of these conditions of the assay would alter the result. A weighed amount of this prepared albumen is dried to a constant residue at the temperature of

212° F. and its weight taken. The albumen not dissolved by the pepsin is filtered out and its weight when dried at the temperature of 212° F. likewise ascertained. From these data is determined the weight of moist egg albumen actually dissolved by the pepsin used, and therefrom the amount of milk sugar necessary to be added to bring the preparation to the standard strength.

MR. BARTLET exhibited his assaying apparatus, which consisted of a sheet iron drying oven heated by a Bunsen gas burner to the desired temperature as shown by the thermometer inserted through its top. Running through the length of the oven is an axis kept in constant revolution by a small water-wheel driven by a jet of water. On this axis revolved a wheel arranged for carrying four two-ounce glass-stopped assay bottles. In this four specimens of the pepsin can be assayed at the same time, and their average taken as the true result. To ensure the most thorough mixing up of the contents of the assaying bottles during their revolutions, three glass marbles are enclosed in each of them. By this method of assay he is enabled to obtain great uniformity of strength, and years of use had proved it to be the most certain method known to him.

MR. BARTLET exhibited a series of pepsin preparations, both solids and liquids.

PROFESSOR MARKOE commended Mr. Bartlet's pepsin preparations and the scientific accuracy of his method of assay.

## Recent Literature.

*Frozen Sections of a Child.* By THOMAS DWIGHT, M. D., Instructor in Topographical Anatomy and Histology in Harvard University, Fellow of the American Academy of Arts and Sciences, Surgeon at the Carney Hospital. Fifteen Drawings from Nature by H. P. QUINCY, M. D. New York: William Wood & Co. 1881. Imperial octavo. 63 pages.

About fifty years ago Blandin's work on Topographical Anatomy appeared in Paris. This was translated by Doane. Together with the writings and classical drawings of Bell, this first introduced the anatomy of regions into English medicine and surgery. Velpeau's Surgery is also distinguished for the clear and concise chapters on the anatomy of the regions subsequently to be dissected in surgical operations. Fergusson's Surgery has similar anatomical descriptions. Later we have Holden's Landmarks partly exemplified on the live subject; a most valuable index of "bearings" for the adventurous mariner on the sea of surgery. All these, however, were based on *dissections*.

The modern school of *sections* had its origin in Russia and Germany during the last fifteen years. Previous topographical anatomy had dealt with surfaces disclosed by dissecting them. This differed from it in cutting through the whole thickness of a head, trunk, or limb, and exhibiting sections of all the contents on one plane surface.

The great Charts of Topographical Anatomy of Life Size by Rüdinger and Braune, although superb, were very expensive, and could only be found in public libraries. An attempt was made to popularize and cheapen them by Bellamy, who published reduced photographs of Braune's Topographical Anatomy.

Ellis's Dissections also furnished a topographical

guide to the surgeon, in a series of fine-colored lithographs, with an exact descriptive text.

The Frozen Sections of a Child, by Dr. Dwight, really marks a new era in anatomy in this country. We believe we are right in saying that this is the first original work on sections published in the United States. As such, and also because it emanates from that medical school which is seeking to imitate the higher European models in scientific medicine, it possesses a peculiar value to us.

The difference between systematic and regional anatomy is very great. The one selects and classifies one group of organs or parts, as muscles, arteries, or nerves, in dissections made for them alone. The other groups all these organs in their proper relations to each other, and dissects them in regions. The one is the anatomy of the student; the other of the practitioner. The one is the anatomy we learn; the other is the anatomy we use. The child can enumerate the rivers of a country; the traveler can alone describe their relations to the surrounding land. The medical student can run off on his fingers the branches of the carotid artery; the surgeon must hold all the relations of the carotid triangle in his mind. Equally important to the physician is a similar knowledge of the deeper regions of the body. The position of the appendix cæci and a clear insight of its relations and proximity to other parts is as vital to the diagnosis of its affections, as the histology of its coats. It is to illustrate such points as these that sections of organs, *in situ*, are so important.

The position and relations of the viscera of the body are so changeable that neither an autopsy nor a dissection can show them uniformly, and as they are in life. Frozen sections supply this want. By their aid every organ can be shown fixed and frozen in its normal position; and it can also be preserved, unchanged, in alcohol, for future study.

"In making frozen sections," says Dr. Dwight, "the body must be precisely in the position you desire, and there must be no folds or indentations in the skin. Natural cold is best, when obtainable, though artificial cold can be employed. The body should be frozen like a rock, so much so that the operator cannot tell whether he is cutting bone or muscle. Tooth is the only tissue he should be able to recognize. The sections should be made in a cold room, with a very sharp saw that has been chilled. When a section is cut, its surface is obscured by a thick, half-frozen sawdust, which is doubly thick if the freezing is not quite sufficient. It is wisest to remove this at once by pouring a little hot water over the section, and brushing it off rapidly and carefully. This is a very delicate part of the process, and its successful performance has much to do with the beauty of the specimen. It is then laid on a piece of glass, and placed at once, while still frozen, in cold alcohol. The specimens from which the plates in this volume are made are preserved at the Harvard Medical School, and are at hand to solve any doubts that may arise."

The body of a child furnishes sections of a convenient size to preserve and exhibit. The differences in the anatomy of the child and the adult are carefully noted in the descriptive text. For the examination and definition of the nerves the child's sections are peculiarly good, on account of the greater relative size and distinctness of the nerves at that age. The locality and arrangement of the *fasciæ* are with difficulty to

be made out, on account of their thinness. This is very unfortunate, as no ordinary dissections display them well, while their relations to other parts are of great importance to the surgeon.

In Plate I. the section passes through the body of the sixth cervical vertebra. The trachea is divided a little below the cricoid. The isthmus of the thyroid appears large. Usually it covers the three rings of the trachea after the first; but it is extremely variable. The left lobe of the thyroid reaches to the œsophagus, and slightly overlaps the carotid. It is easy to see how, if enlarged, it might make its way between the artery and the vein. This we have once found it to do in operating for the removal of goitre.

This plate also shows that the sheath of the carotid must not be considered as a membranous tube, but rather a collection of dense areolar tissue surrounding the artery, vein, and nerve, and running in between them.

The section in Plate II. is about two centimetres below the first one. Among other things it shows well the apices of the lungs rising above the clavicle, — they reach to the level of the head of the first rib, — or some three fourths of an inch, and sometimes more, into the neck. Here their surgical relations to the subclavian triangle are of importance.

The deeper layer of the cervical fascia is shown to be continuous with the costo-coracoid membrane. It is continued into the axilla, forming the front of the sheath of the axillary vessels. The prevertebral fascia is very dense, and sends prolongations to the roots of the lungs, to the pericardium, and to the diaphragm. They may be called suspensory ligaments, and prevent sinking of the tendinous centre of the diaphragm. This plate shows how exposed the deltoid muscle is to injury in falls, or blows on the shoulder. Wasting after injury may be due to direct injury of the muscular fibre, as well as to the circumflex nerve.

The relations of the long thoracic nerve to "angel palsy" are also shown.

The thymus gland is shown in Plates III. and IV. This organ is often found in the young adult. Rüdinger says its involution does not begin until the fifteenth year. In the neck, the deviation of the œsophagus to the left deserves special mention in Plates I. and II. An examination of sections by Pirogoff, Braune, Rüdinger, etc., shows, however, great variation. A small bursa between the humerus and the pectoralis minor is to be noted. A small space is to be seen under the scapula, bounded by the chest, the rhomboid, and the serratus, where pus is occasionally found, and as the serratus does not allow the abscess to point in the axilla it may attain a large size.

In Plate IV. the aorta arises on a level with the upper border of the cartilage of the fourth rib. The height of the arch of the aorta behind the sternum varies much. In thirty instances out of forty-eight, however, the top of the arch averaged half an inch below the top of the sternum. The relations of the pulmonary arteries, veins, and bronchi, as well as the relative positions of the aortic and tricuspid valves, are demonstrated in this section, and in Plate V.

Usually, as we are shown, a needle thrust through the fifth or sixth intercostal space, and sometimes through the fourth at the left border of the sternum, will pierce the pericardium and not the pleura.

In Plates VII., VIII., and IX. the extent to which the pleural cavities extend downwards is demonstrated.

They do not follow the diaphragm into the angle which it forms with the cartilages of the six lower ribs; the very lowest part of this space is filled with areolar tissue.

The pleura lies behind both kidneys, but covers more of the right one. It reaches the upper border of the last rib, near its beginning, but the rib soon runs away from it.

A case has been reported in which a surgeon operating in the lumbar region, to reach the kidney, mistook the eleventh rib for the twelfth, and by carrying his incision toward its lower border opened the pleura. Plate IX. shows that such an accident might take place. The spleen is shown to be wholly under the cover of the ribs. The views of the stomach (page 37) are very instructive. They confirm Luschka's statement that the fundus points upward, and that the lesser curvature is essentially vertical. Five sixths of the stomach are on the left of the median line. The pylorus is opposite the first lumbar vertebra. The pylorus is usually found between the ensiform cartilage and the right costal arch. The lesser cavity of the peritonæum and the foramen of Winslow are well displayed.

One of the most important parts of Plates IX. and X. are the views of the duodenum. The opening through the pylorus looks directly backward. Both ends of the duodenum are at the same level, and both are somewhat fixed points; one end attached to the stomach, and the other suspended by muscular fibres from the celiac axis and the crus of the diaphragm. The remainder of the duodenum is pretty freely movable; it has been compared to a horse-shoe. The positions, covering, and mobility of the kidneys are shown in Plate X. Mobility is commonly due to loss of firmness in the areolar tissue around the kidney, and especially to the loss of fat.

The muscular triangle of Petit is shown. The erector spinae is subdivided and described by a new nomenclature.

The umbilicus is opposite the level of the third and fourth lumbar vertebrae. The cæcum is on a level with the umbilicus (Plate XI.).

The relation of the peritonæum to the descending colon is shown. The extent to which it covers the gut varies extremely, and at all ages.

The lumbar fascia is described. The laws of curvature of the spine are discussed at length on page 50.

The author thinks the male sacrum is more curved than the female.

The ovaries are shown descending into the pelvis, in a manner analogous to the descent of the testes. The fundus of the bladder, the *trigone*, and the ureters are considerably discussed on page 58. The distance of the pouch of peritonæum above the anus varies with age.

The third sphincter and of modern authorities is a mere thickening of muscular fibres, of no great power. The upper part of the rectum has a true mesentery, which permits moderate displacement.

"It has been demonstrated," says Dr. Dwight, "that the whole hand can be introduced into the rectum; and also that it had much better not be, unless the information to be gained is of sufficient value to justify risking the patient's life to obtain it."

The drawings of Dr. Quincy, favorably known here as a devoted anatomical artist, are excellent. They are of life size, clear, and taken from nature. The typograph-

ical execution of the book, by William Wood & Co., merits praise also for its neatness and accuracy. In short, we find little to criticize in a work so novel here, and sincerely congratulate the author on his industry, enterprise, and research. It requires these qualities, as well as a love for pure anatomy, to make a study of such a subject and to publish it. This book will be useful to students and to practitioners alike. It is to be hoped that it may be the forerunner of other and fuller treatises on topographical anatomy as time goes on.

Nearly twenty years ago the writer of this review began, and continued for fifteen years, a short annual course of dissections and lectures on regional anatomy in the Harvard Medical School. They naturally took a more practical and surgical bearing than a purely topographical one. Convinced of his inability to devote time and acquire knowledge in this vastly growing department of anatomy, adequate to give proper instruction in it, and deterred by other and pressing duties, he resigned this pleasant task to younger hands, and the event has proved the wisdom of so doing.

D. W. C.

*The Opium Habit and Alcoholism.* By F. H. HUBBARD, M. D. New York: A. S. Barnes & Co. 1881. 259 pages.

The author states that he has sought to place in the hands of the profession a carefully arranged analysis of the subject. This he has hardly succeeded in doing, many portions of the work being indefinite if not unintelligible. For example, in Chapter XIV., on the influence exerted by opium over cancer, is the following carelessly written prescription:—

|   |                |       |        |
|---|----------------|-------|--------|
| ℞ | Iod. pot.      | ..... | 3j.    |
|   | Bi. chlo. hyd. | ..... | gr. i. |
|   | Tr. iodine     | ..... | 3v.    |
|   | Aqua           | ..... | 3v. M. |

Sig. One teaspoonful in a wineglass of water.

And after it this explanation: "This was given to assist in destroying and eliminating from the system morbid products that possess *extratic* activity when deposited, as they are then transformed into an organized, adventitious mass, having within itself the power to add to morbid accumulations, or act as a nucleus for a new growth."

The book will not repay the time required for its perusal.

*The Therapeutics of Gynecology and Obstetrics, Comprising the Medical, Dietetic, and Hygienic Treatment of Diseases of Women.* Second Edition. Edited by WILLIAM B. ATKINSON, A. M., M. D. Philadelphia: D. G. Brinton, 115 South Seventh Street. 1881.

The second edition of this work presents considerable new matter, and this keeps pace with the new and improved methods of treatment. In so catholic a work, drawing its material from all sources, there must be necessarily a good deal of chaff mixed up with the wheat. To the general practitioner, however, who cannot acquaint himself with the various methods of treatment in this specialty from the original sources, this book will prove a valuable one to consult. In the absence of any careful discussion of the value of the different measures advocated, the high standing of the authors quoted must largely determine their relative merits.

# Medical and Surgical Journal.

THURSDAY, MARCH 9, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

## THE MEMORIAL HISTORY OF BOSTON; THE CHAPTER ON MEDICINE.

THE method of writing books by a coalition of writers, to whom different subjects are assigned, under the direction of a skilled director, is a very familiar one to medical men; applied to history the method is new, and so far as the first venture of the sort is concerned most certainly successful, if we may judge from the many favorable notices of the daily press and the numerous schemes for its application to other and perhaps wider subjects. To it we are certainly indebted for a very interesting chapter on Medicine in Boston by our former City Physician and present Mayor, Dr. Greene, to which are appended some additional memoranda by Dr. Oliver Wendell Holmes. Probably no two men could have been found who would have treated the subject more intelligently and more delightfully. For a medical man to say that the chapter is one of the most interesting of the four volumes is to say little more than that it treats of a subject which appeals particularly to his taste, but he might certainly venture to say that it ranks high among the various articles for fullness of detail and picturesqueness of representation. As a single chapter in a general history it necessarily leaves unnoticed many minutiae which a careful student of medical history would expect to find in a work specially devoted to the single subject, but intended, as it is, for general readers, it contains much that is most generally interesting and in most delightful dress. The chapter abounds in quaint quotations from the older medical men which add an additional charm to the narrative and testify to the extensive researches in the library of the Historical Society by its accomplished librarian.

With Giles Firmin, Jr., and the anatomy which he did make probably all the readers of the JOURNAL are familiar and how he did read upon it very well in the opinion of the apostle Ehot; our interest in the first anatomy maker is greatly enhanced by his own words, which are quoted by Dr. Greene: "*I am strongly set upon to study divinity, my studies else must be lost; for physick is but a necesse helpe.*" It seems that even then the acquisition of an income was by no means sure, and we speculate in vain on the cause of his failure; did he think that because he could make an anatomy he was therefore entitled to the patronage of the sick; he too may have left his dissection with regret and have said with John Hunter, though with language better fitted, let us hope, to the tongue of one who would minister in sacred things, that he

must go and earn that unblessed guinea; it may be that the complaints of the good wife fell upon an inattentive ear when she detailed all she had done before she called the chirurgion, and that the leech, who cared naught for anatomie-making but whose skill lay in the concoction of soothing possets, and who listened patiently and with a grave countenance, found the profession remunerative, while to our poor Giles it was but a "meene helpe;" or can it be that he had acquired expensive and luxurious habits in England which divinitie promised to gratify with less exertion, and which led him eventually to return to the mother country?

It is surprising in these days of lengthening courses, foreign study, and exclusive devotion to restricted portions of what we are pleased to term the broad field of medicine, to see how easily our predecessors carried the burdens of a double and even a triple profession. The reverend and learned Mr. Nathaniel Williams, the master of the Free Grammar School, from 1708 to 1734, was preacher and school-master as well as "a very skillful and successful physician." The conjunction was not always so noble a one; if we may credit the records Margaret Jones of Charlestown practiced witchcraft as well as physic and was hanged for the former offense. She was wise in her generation evidently, and those who refused to take her medicines found that their "diseases and hurts continued, with relapse against the ordinary course, and beyond the apprehension of all physicians and surgeons." Perhaps Margaret Jones would hardly have been recognized at a later time as a member of the fraternity, but educated physicians were rare in the older days. At the date of the introduction of the variolous inoculation there was but one regularly educated physician in the Province, Dr. William Douglass, who was wittily described by a contemporary, and the historian seems to think there was possible ground for the description, as "always positive and sometimes accurate."

The additional memoranda by Dr. Holmes bear more particular but by no means exclusive reference to the present century, though such a division is not accurately followed nor probably intended by the authors. Dr. Holmes dwells somewhat at length on the changes in drugs and methods of procedure, and gives more particularly and most interestingly his personal reminiscences of men who were known to the eldest among us, and whose names are familiar to us all, and it is wholly unnecessary that they should wait, as their author suggests, to gather interest by the lapse of years.

The chapter can but be exceedingly interesting to members of the profession, and we trust it will do much to help non-professional readers to a better understanding of medicine and medical men.

— At a stated meeting of the New York Academy of Medicine, held March 2d, Dr. Frederick A. Castle read a paper entitled, Some Practical Suggestions in the Treatment of those Diseases of Women which every Physician may be Called upon to Consider.

## MYXŒDEMA.

In 1873 Sir William Gull reported before the Clinical Society of London five cases illustrating what he described as "a cretinoid state supervening in adult life in women." Though regarding the conditions observed in these cases as characteristic of a well-defined and individual disorder, the word "cretinoid" was applied to them by Sir William simply as descriptive of the appearances of the patient, but by no means as suggestive of the aetiology or pathology of the disease, if such further observations should prove it to be.<sup>1</sup>

Dr. Morvan, of Lanniles, in France, is said to have reported fifteen cases closely resembling those of Sir William Gull's in 1875; of these we have seen a general description,<sup>2</sup> but have not been able to refer to the cases themselves.

In October, 1877, four years after Sir William Gull's cases, Dr. William M. Ord, of London, read a paper before the Medico-Chirurgical Society<sup>3</sup> devoted to an account of five of these cases which had fallen under his observation during the preceding twelve years, and applied to them the name myxœdema. Since then cases have been reported by Charcot in France, and by several physicians in England, — notably by Drs. Goodhart,<sup>4</sup> Lunn, Cavafy, Ord,<sup>5</sup> and Mahomed,<sup>6</sup> — more or less resembling each other and those first referred to.

The references we have given cover pretty much the entire literature of myxœdema, which is evidently not extensive. We are not aware that any cases have been reported in this country, or that the peculiar conditions described have attracted the attention of American physicians. The cases presented by Drs. Ord, Cavafy, and Lunn at the meeting of the Clinical Society, December 9, 1881, brought on a debate at the subsequent meeting, Dr. Mahomed taking the ground that the collection of symptoms constituting myxœdema were but manifestations of chronic Bright's disease. His opponents, though acknowledging a considerable variety in the cases, were generally disposed to consider it as a distinct disease.

Among Dr. Ord's cases reported in 1877 was one accompanied by an autopsy, performed by so competent a pathologist as Dr. W. S. Greenfield, and a microscopic examination of the œdematous tissues. The more important details of the post-mortem examination were: (1) there was general œdema of the skin, but the cut surfaces yielded less fluid than their appearance would promise; (2) there was much serous effusion in the pleura, pericardium, and peritoneum; (3) the heart was large, weighing sixteen and one half ounces, the left ventricle hypertrophied, the valves practically healthy; (4) the arteries were everywhere thickened, the larger ones atheromatous; (5) the cortical substance of both kidneys was much wasted, and granular both on surface and on section, the renal

arteries were thickened and atheromatous; (6) there was a firm, almost solid, œdema in many parts, for example, in heart, soft palate, stomach, and neck of bladder; (7) the brain showed very considerable degeneration of the larger arteries. In preparing portions of the organs for microscopic observation it was noticed that the skin in particular retained its œdematous condition even when cut up into small fragments. Upon subjection to the same process in equal proportions, the skin of Dr. Ord's patient yielded mucin to fifty times the amount obtained from the skin of non-œdematous or simply œdematous bodies.

Sir William Gull's cases<sup>7</sup> were all middle-aged women, and he described the general aspect of the disease as "a cretinoid state supervening in adult life in women." Dr. Ord's early cases were also all five women between forty and sixty years of age; as, indeed, most of the clearly defined cases since reported have been. In the light of further investigation, supported by his autopsy, Dr. Ord was led<sup>8</sup> to make the suggestion that the whole collection of symptoms are related as effects to jelly-like swelling of the connective tissue, chiefly, if not entirely, consisting in an overgrowth of the mucus-yielding cement by which the fibrils of the white element are held together. He accordingly proposed the name of myxœdema for the affection; and argued that the most important mode of operation by which this condition produces the symptoms associated with it is the padding of the periphery termination of sensory nerves, and perhaps, too, of muscular nerves, with a soft material which hinders their free reception of impressions, in the same way as cotton wool in the external auditory meatus deadens sound on its passage to the auditory nerve. That perception becoming slower than usual, and the central nervous system losing, through the altered state of the skin, its natural and necessary stimulation, a state of intellectual lethargy and a slowness in coördination of movements are necessary consequences. In this chain, slow use, partial disuse, and numbness of faculties are links of one kind, and the constant retardation of guiding sensory impulses, a link of another, so that, supposing the myxœdema to be constant, the nervous degradation tends to be progressive. The train of symptoms leading to the fatal termination commences in the encroachments of the myxosis upon vessels and upon the secreting elements of glandular structures. The two fatal cases of Dr. Ord showed at the last the symptoms associated with renal disease.

The debate on myxœdema at the Clinical Society of London, last December, was started as we have said, by a suggestion from Dr. Mahomed that the cases reported under this name were really chronic Bright's disease. This view he supported, remarking that, in many cases of Bright's disease, there was an absence of œdema, but in others there were all the symptoms of myxœdema, without albuminuria, but with high arterial tension. In one case the subcutaneous tissues were not found to contain mucin. The cases appeared to be due to chronic Bright's disease without kidney-symptoms, as described by Sir W. Gull and Dr. Sutton. In the

<sup>1</sup> Clinical Society Transactions, vol. vii., 1874.

<sup>2</sup> Gazette des Hôpitaux, September 24, 1881.

<sup>3</sup> Medico-Chirurgical Society Transactions, vol. lxi., 1878.

<sup>4</sup> Medical Times and Gazette, 1880, vol. i., p. 473.

<sup>5</sup> British Medical Journal, 1881, vol. ii., p. 1017.

<sup>6</sup> Lancet, 1881, vol. ii., p. 1078.

published cases of myxœdema, now twenty in number, three were not noted as to urine; in the seventeen others, ten had albuminuria, of which four were fatal; they had affected kidneys, hypertrophied heart, and thickened arteries; whilst many of the changes in the spinal cord were doubtless those of myxœdema of the cord. Thus in all the four fatal cases Bright's disease was present. Albuminuria was absent in many cases of Bright's disease. And if there were such a thing as local œdema taking place, it would be a good explanation of nervous symptoms developed in myxœdema.

In a paper subsequently contributed to the *Lancet* [December 24, 1881] on the subject, Dr. Mahomed added to the previous twenty cases the seven discussed at the Clinical Society, making in all twenty-seven cases, in fifteen of which he finds that albuminuria or other good evidence of Bright's disease existed during life, while it was present in all of the five fatal cases reported. Sphygmographic evidence of the degree of arterial pressure is difficult to obtain, owing to the thickening and infiltration of the tissues.

The other gentlemen taking part in the debate were none of them inclined to agree with Dr. Mahomed in his view of the subject, and seemed disposed to think that he was attempting to cover too much ground by the doctrine of arterio-capillary fibrosis; and he himself admits, in concluding the paper above referred to, that even should we seem justified in regarding this condition as a result of chronic organizing œdema due to Bright's disease or other causes, the curious and characteristic symptoms which such cases present well deserve that they should be recognized by an appropriate title. Should an excess of mucin in their tissues prove to be a constant feature, nothing could be better than the name given them by Dr. Ord, to whom we are so much indebted for their careful investigation; it has the great merit of describing an anatomical characteristic without implying a theoretical explanation. At the same time he ventures to express a fear that we may be led to regard as a disease what may be only a symptom; besides giving rise to erroneous views concerning its pathology, such a belief would obviously tend to narrow our conception of its clinical import, and of the very varied conditions, requiring equally varied treatment, under which it may possibly occur.

Dr. Ord's summary of the clinical and pathological characters of myxœdema, in closing the debate, was clear and concise, and gives a fair idea, in a general way, of what is at present known about the affection. The subjects were generally women; there was *never* albuminuria in the *early* stages; nor, in some cases, at all; there was general swelling of the integuments, which were semi-transparent, rough, and non-perspiring; the hair was scanty; the teeth bad; the temperature low; the thyroid small; the speech slow, imperfect, and nasal; thought and perception slow, but perfect. The patients were apt to become irritable and timid, sometimes demented, and finally comatose. Occasionally death arose from general debility, sometimes from uræmia. Throughout the body the interstitial tissue was swollen and nuclear, increased in quantity,

and containing mucin; it encroached on all the normal structures, which became atrophied, as in the case of the hair, the sebaceous and even the sweat glands, the heart, liver, and other internal organs. The idea that this was Bright's disease without albuminuria was soon negatived. The theory of sympathetic origin did not commend itself to him, for there was no evidence that the sympathetic had trophic functions. Probably, as regards the nervous system, the central organs were affected in the same way as were the peripheral. Dr. Ord did not think, however, that the change was due to a degeneration, but rather to a malformation of tissue. The question of heredity was new. He was not prepared with any special theory to explain the disease in its totality.

This subject is one which deserves and will probably attract further attention, the advantages in the discussion so far being decidedly with those who regard myxœdema as a distinct and independent disease, and it is an important point to bear in mind that even in the cases where it has appeared at all the albuminuria has been almost always a very late development.

#### MEDICAL NOTES.

— Some exceedingly interesting photographs of small-pox eruption from the third to the fourteenth day, the work of Mr. S. A. Powers, of the Small-Pox Hospital, may be seen at the Medical Library.

— Joseph Pancoast, M. D., Emeritus Professor of Anatomy in the Jefferson Medical College, died at Philadelphia last Tuesday morning, aged seventy-seven.

— The Woman's Medical College of Baltimore has recently been incorporated. The course of lectures will begin October 1, 1882. Seven professors, all of them gentlemen, have been already appointed.

— The Paris Académie des Sciences has conferred on Professor Brown-Séquard the distinguished honor of the Grand Prix Lecaze. This prize, which is of the value of ten thousand francs (four hundred pounds), is given only in recognition of a lifelong devotion to physiological science, which has resulted in important discoveries. The previous recipients have been Chauveau, Marey, and Dastre.

#### NEW YORK.

— At the last meeting of the County Medical Society Dr. George H. Fox read a paper on the permanent removal of superfluous hair, with reports of cases, and Dr. A. Jacobi, the late president of the State Medical Society, a paper on legislation looking to the establishing of special hospitals for scarlet fever and diphtheria, and also for the protection of factory children.

— During the month of February 21,033 persons were vaccinated by the officers of the Health Department, free of charge, and the sum of \$2311 was received from the sale of vaccine virus.

— Over forty classes are now being instructed by physicians under the auspices of the First Aid to the Injured Society, which has been organized upon the

English plan, and of which General George B. McClellan is the president.

—A moving story comes to us of the sufferings of an unfortunate lady in a village in the northern part of New York State, who was recently taken violently ill, and when the local physician arrived confided to him the startling intelligence that there was a snake in her stomach, which she had swallowed last September while drinking from a brook. The report goes on to state that the doctor, upon investigation, "became satisfied that the woman had swallowed a tadpole, which has since turned into a frog," and that the presence and movements of the reptile in the stomach can readily be felt from the outside. The patient is to be taken to the hospital in Albany for treatment, and the subsequent developments of the case will, no doubt, be awaited with no little interest.

#### MEDICO-LEGAL NOTES.

*Forcing Prisoner to show Himself.* — In a criminal case the place at which the prisoner's leg was amputated being a material point, it was decided by the Supreme Court of Georgia to have been an error in the lower court to require him to show himself, so that a witness could see him and describe his condition to the jury. A defendant in a criminal case cannot be required to give evidence against himself, either by acts or words.

*Anæsthetics from a Medico-Legal Point of View.* — Dr. J. G. Johnson, of Brooklyn, presents certain conclusions in the *Annals of Anatomy and Surgery* which deserve careful consideration.

Anæsthetics do stimulate the sexual functions, the ano-genital region being the last to give up its sensitiveness. Charges made by females under the influence of an anæsthetic should be received as the testimony of an insane person is. It cannot be rejected, but the *corpus delicti aliunde* rule should be insisted on. Dentists or surgeons who do not protect themselves by having a third person present do not merit much sympathy.

Death from administration of chloroform after a felonious assault, unless the wounding were an unmistakably fatal one, reduces the crime of the prisoner from murder to a felonious assault.

The surgeon has no right to use chloroform to detect crime, against the will of the prisoner.

But the army surgeon has the right to use chloroform to detect malingerers.

The medical expert, notwithstanding he is sent by order of court, has no right to administer an anæsthetic against the wish of the plaintiff in a personal damage suit, to detect fraud.

Gross violations of the well-known rules of administering anæsthetics, life being lost thereby, will subject the violator to a trial on the charge of manslaughter.

A surgeon allowing an untrained medical student to administer anæsthetics, life being lost thereby, will subject the surgeon himself to a suit for damages. What he does through his agent he does himself.

The physician who administers an anæsthetic should attend to that part of the business and nothing else. He should have examined the heart and lungs beforehand. He should have the patient in the reclining position, with his clothes loose, so as not to interfere with respiration; should have his rat-tooth forceps, nitrite of amyl, and ammonia, and know their uses, and when to use them, and how to perform artificial respiration.

Chloroform cannot be administered by a person who is not an expert to a person who is asleep without awaking him. Experts themselves, with the utmost care, fail more often than they succeed in chloroforming adults in their sleep.

#### Dissection.

#### THE CASE OF GUITEAU.

MR. EDITOR, — I have read with great interest Dr. Folsom's carefully prepared article which appeared in your issue of February 16th, relative to the case of Guiteau, and having had occasion to examine the prisoner upon three separate occasions, as well as having watched him in court for more than three weeks, I desire to say a few words more, especially in regard to the physical appearance of the assassin, believing that it does not reveal any indication of congenital or acquired mental disease.

My visits to the jail were made with the view of discovering any possible external expression of insanity, long before the question of cranial asymmetry had been raised at all. The examinations were made in the presence of several witnesses and I was assisted

by Dr. Kempster, of the Wisconsin State Asylum, a most careful observer and student of craniology, and by others.

Charles Julius Guiteau, aged forty years, is of spare build, of nervous temperament, weighs one hundred and thirty-five pounds, and is five feet five and three

quarter inches in height. He is badly nourished and anæmic.

In appearance he resembles the criminal known to the police as the "sneak," and his physiognomy is one more familiar to the visitor at the prison than the asylum. The facial lines are deep, and express the constant exhibition of the baser emotions. There is a slight furrow between the brows; the nasal lines are deep, the nose thin and pointed; and the lips are thin and usually slightly parted. His hair is short and mixed with gray, and so cut as to give some appearance of flatness to the top of his head. At the anterior part of the left side of the head is a slightly depressed scar about three cm. long, the lower edge being about nine cm. above the centre of the external auditory meatus, and the superior extremity about six cm. below the longitudinal median line. There is no evidence of premature closure of the sutures, no bregmatic depression, and no cranial exostoses. The conformation of the head is no way atypical, neither *brachy-cephalic* or *dolicho-cephalic*. (See plates.) The basal circumference is 55.9 cm. The antero-posterior arch 20.2 cm.; the transverse arch 16.5 cm.; the basal antero-posterior diameter 19.5 cm.<sup>1</sup> A *con-*

*conformation* measurement taken at a higher level posteriorly at the plane of the parietal eminences reveals no special asymmetry.<sup>2</sup>

<sup>1</sup> It has been stated by a writer in the *New York Medical Record* that my measurements were made at so low a level as to prevent me from recognizing the existence of an alleged ridge of bone passing across the back of the head. The writer was not probably aware at that time that this *conformation* measurement was taken at the high level, but nothing was shown. I would take this occasion to refer to the trick of the prisoner's counsel, who placed the *conformation* tracing over the above—of course they did not agree.

<sup>2</sup> Clapham (W. R. Reports, vol. vi., 1876, page 150), gives some tables of skull measurements. He found that a man weighing 130-140 pounds should have a head of circumference of 21.253 inches. A man 65 inches high should have a head of circumference of 22.616 inches. It will be seen that the head of Guiteau was of fair size according to Clapham's figures.

There is slight fullness on the right side both anteriorly and posteriorly. I did not calculate the facial angle, there being nothing to attract attention. There is no appearance of *hamutoma auris* or crenation of ears so often found in the chronic insane, and his skin showed no abnormal change, being moist and not scurfy. The fingers were devoid of ungual defects, there being no languails, no clubbing, no temperature nor circulatory changes. The teeth are regular (I cannot agree with Dr. Folsom as to any conspicuous projection) but the two first incisors in the upper jaw are separated by a slight fissure which increased the malignity of the prisoner's facial expression when his mouth was open. The bark teeth are carious. There is no abnormality in the roof of the mouth, no extreme vaulting of the palate process of the superior maxillary bone, and no fissure.

When the prisoner was told to open his mouth he did so, and the opening was symmetrical, there being no defective muscular antagonism. Upon my first visit I found what appeared to be a fine fibrillary tremor in the upper cheek-muscles, and eyelids, but this was after an exciting day in court, and I never saw it again. The unequal tremor of the tongue, alluded to by Dr. Folsom, was not observed by me except upon this occasion, and it was not manifested except when the tongue was kept protruded for some time. In no respect did it resemble the tremor of general paresis, and it was not accompanied by tremor of the lips. The tongue was protruded slightly to the left side, but there was no atrophy whatever, and it could be freely pointed to the other direction, and its tip approximated to the roof of the mouth. I tested his speech carefully, but found no impairment, but in court he momentarily hesitated because his ideas were evolved too rapidly, and the function of the cerebral speech centres did not seem to keep pace. A careful ophthalmoscopic examination failed to reveal any neuritis or atrophy, and Dr. Loring was equally unsuccessful in making any discovery of ocular trouble. We found him to be hypermetropic, and the left eye was the seat of conjunctivitis at the first visit, and quite sensitive, and as a result the pupil was slightly contracted, but only upon one occasion was this observed, his pupils being afterwards normal, and contracting perfectly to diffused and artificial light. The pupils were not contracted as is the case in the early stage of general paresis.

Tests of motility were negative. He walked well without any drag, and there was no disturbance of co-ordinating power. I tested the tendon reflex in the extremities both by Buzzard's and Gower's method, and in the ordinary way, and I failed after repeated examination to discover any abnormal increase, and light and heavy blows failed to evolve a *jerk* of any kind, but there was moderate responsive action, equal on both sides, with no secondary jerk. Hand grasp unaffected, and he could localize small objects. Hearing was normal. Retains urine for several hours even when excited, and when passed it is neither forcibly ejected nor does it dribble. He says he has had a gonorrhoea, and his stream is spiral, so he probably has some stricture. He denies *absolutely* that he has ever had *syphilis*, and no evidences are found. He has a small herpetic patch on the forehead, but this is probably due to his depraved physical condition. There is no evidence to show that he has indulged in bad sexual habits in jail. Pulse found to be 88 upon

two occasions. Temperature taken daily by jail physician shows no abnormal rise.

It would be going over much wearisome ground to again attempt to analyze the evidence introduced in court except to insist upon what I believe to be the truth, that he is an eccentric criminal, who has been playing a part in court that might at least (if not humbling the experts) affect the jury, and gain for him a disagreement.

None of the expressions of disorderly mental action upon the part of the prisoner, either isolated or with others, were, in my opinion, incompatible with sanity, nor indications of any known mental disease. The evidence brought forward was such as to show that the prisoner had been brought up badly, and had, from the time he began to look out for himself, lived as a parasite upon society, making use of all methods of shrewdness and deception to gain shelter and food, until he found his path in life becoming more and more difficult to follow, and then he resorted to more desperate measures. Like the murderers in *Macbeth* he might have said:—

"I am one, my liege,  
Whom the vile blows and buffets of the world  
Have so incensed that I am reckless what  
I do to spite the world."

"And I another, so weary  
With disasters, tugged with fortune,  
That I would set my life on any chance  
To mend it, or be rid on't."

When we analyze his actions I do not think there is any alternative for us. We can only say that his crowning crime was the culmination of uncontrolled wickedness, and his conviction and sentence the natural result of the failure of his last desperate scheme.

Thomas Beggs Gilpin,<sup>1</sup> in speaking of the psychology of crime, says, "It matters not what may be the character of the crime; it may be arson, it may be rape; the first successful gratification of vindictive feeling leads by similar progression to the one; the first flirtation of simple sensuality, unchecked, if not encouraged, leads by the like gradation to the other; in all cases progress from venial to bad, from bad to worse, and thence to extremes, is the invariable trait of a criminal career; consequences are first calculated with anxiety, then merely weighed against immediate gain, and finally disregarded altogether."

There are thousands of men at large to-day who display all the eccentricity of Guiteau, but their actions are as impulsively good, or at least their intentions are as well meant, as his were bad, and still they are not called insane. In some cases these persons are reformers, with projects in every way as absurd as any of Guiteau's. What can be said of the educated individual, for example, who advocates the abolition of vaccination?

Guiteau is only a shrewd scamp, with the plausibility of an Alfred Jingle in swindling his boarding-house keepers, and evading the payment of his debts; the visionary enthusiasm of Micawber or Colonel Sellers; the cant and hypocrisy of Aminadab Steek or Uriah Heap; the ambition of Erostratus, and the murderous manners of Felton, who assassinated the Duke of Buckingham, of whose crime the killing of Garfield was an almost exact counterpart.

None of his "delusions" were akin to those of gen-

eral paresis of the insane, for in that disease there is no reasonable basis whatever, and, moreover, if Guiteau is a general paretic, as Dr. Folsom suggests, his boasting and immense projects have been expressed for at least twenty years, and there are few cases of general paresis that live beyond the tenth year of the disease, and they nearly all end fatally in three or four years, or less. Guiteau's projects were, as a rule, substantial, and were at some time realized.

The *Inter-Ocean* scheme was a pronounced success, the *Theocrat*, conducted, perhaps, in a more modest way than Guiteau might have wished, had an existence of several years as the *New York Daily Witness*, a small religious daily paper, and even his last and most fatal "delusion" was verified, for he *did* "unite the Republican party," and his act has thoroughly changed the features of American politics. In some countries where a president is assassinated every year or two, he might even have become the martyr he expected to be, but, unfortunately for him, his own was not one of these.

Dr. Folsom<sup>2</sup> very aptly says, "His shooting of the President was, to a certain extent, the logical result of bad training, character somewhat unscrupulous, enormous self-conceit, self-will, disappointment in not getting office, cowardice, extreme political partisanship, delusions or deceit regarding religion, desperation of poverty, expectation of personal gain, love of notoriety, and hope of praise from the 'stalwarts,'"—but are these necessarily expressions of insanity?

I should have been far better satisfied had Guiteau really been found insane, but I feel that viciousness and lawlessness must occasionally find vent, and we have to congratulate ourselves, under the circumstances, upon the comparatively few exhibitions of the kind that have hitherto thrilled us with horror.

While I do not agree with an English criticism that "Guiteau is a type of American civilization," I do believe that in a new country as large and great as ours, a land in which religious and political liberty is as universal as it is in this, and in which the creed that "one man is as good as another," has so many believers, there must be many Guiteaus; not Guiteaus who necessarily kill a president, but eccentric individuals with "badly arranged winds." In many sections of the country there are religious sects and communities whose teachings are as immoral and unstable as that of the establishment at Oneida, from which the assassin graduated. In the section in which the elder Guiteau lived I understand that a large number of people, even to-day, hold that with careful bodily care, life may be prolonged indefinitely, but the counsel for the prisoner inadvertently proved, in alluding to the elder Guiteau's views on this subject, as an element of his insanity, that he nevertheless made a will and insured his life. In your own State there is a body of "Second Adventists," many of whom, I understand, fully approved at the time the crime of Freeman, who sacrificed his child, and in other parts of the country there are colonies of equally ignorant and fanatical people, whose teachings and practices are calculated to stimulate the baser emotions of the ignorant, and send them adrift to prey upon society, with the most loose views both religious and ethical.

In conclusion I desire to express my conviction that we should not permit ourselves to confuse the crime

<sup>1</sup> Forbes Winslow's *Journal of Psychological Medicine*, vol. v., p. 177.

<sup>2</sup> *Boston Medical and Surgical Journal*, February 16, 1882, page 151.

which is the result of a low state of the morals for which the individual is solely responsible, with that moral perversion which is associated with intellectual insanity, and which is the product of a diseased brain.

Very truly yours,

ALLAN McLANE HAMILTON.

NEW YORK, February, 1882.

### IS SCARLATINA CONTAGIOUS?

MR. EDITOR.—The books say so. The prolix Ziemssen, whose learning often smothers his knowledge, says so. The Massachusetts Board of Health says so, and I bow to the Board of Health, accepting their dictum as a dogma, without having seen evidence, without knowing their reason, and, therefore, without reasonable conviction. Accordingly I isolate my patients, and keep families of children from school, and practice such disinfection as does not involve waste nor cruelty, endeavoring always not to add to the terrorism which extraordinary measures are liable to develop. But yet in more than forty years of experience, and much of it on a large scale, I have failed to see the evidence of contagion in scarlatina.

I have just ceased attendance on a man sixty years old sick with scarlatina. The eruption was general and vivid and persistent, the fauces inflamed, the constitutional disturbance great, the convalescence protracted, and the desquamation in large patches. In this man's family, twenty-five years ago, I attended five children with scarlatina. The sickness was in narrow quarters, and covered several weeks of time, during which both father and mother were over the patients almost constantly. The disease was also grave, one case terminating fatally within twelve hours after the invasion. Both parents escaped the "contagion," and the father had the disease twenty-five years later, after no known exposure, and when his improved circumstances had placed him in a much more wholesome habitation.

Thirty years ago one of a pair of twins, aged three years and inseparable, had scarlatina under my care. These children were in excellent sanitary surroundings. The other twin did not contract the disease then, but had it a year later, when there was no scarlatina in the neighborhood.

I have just come from a boy thirteen years old, sick with tonsillitis. On inquiring of his mother if there was any scarlatina in the neighborhood, she reminded me that he had had this disease several years ago, when there was no other case in town so far as we knew.

I have recently attended a young man with scarlatina in the Jesuit College here. This building has a population of one hundred and more in priests, professors, pupils, and lay brethren. The College is situated on a high hill, in a field of many acres, with no dwelling house within a quarter of a mile, and the patient had been in no dwelling house whatever for three weeks, and then only for a few moments in a house where there was no sickness. His disease was mild. I placed him in a separate room, isolating him as well as I could on a common corridor, and he did well, and no other person in the house had the disease.

I state these cases not as proving anything conclusive. They certainly do not prove contagion. They are of a large class of cases familiar to physicians whose practice covers a considerable period of time. And I find that the longer and the larger and the more

intelligent the practice the less is the confidence in the contagion of scarlatina.

It is much easier to get together facts bearing on a question like this in a country town than it is in a large city, where one may be jostled on the sidewalk by a man who has varioloid.

It is, perhaps, natural that we should look upon the diseases which, as a rule, we have only once, as derived from and containing and evolving contagious elements. And this may generally be true. But such diseases are always of epidemic as well as of contagious character. The epidemic influence is one which we cannot understand nor measure. The contagious influence has certain laws, and operates usually by a period of incubation which is determined and well known. Thus, many years ago, at a meeting of our local Society for Medical Improvement, I mentioned my having been called that day to a case of measles, while I had seen no case before for several years, and I inquired if other gentlemen had recently seen measles. Immediately it was ascertained that within two or three days measles had settled down upon the whole town. Now here is an instance of what is called spontaneous development by epidemic or endemic influence, and wholly beyond our power to understand or explain. And then each individual patient becomes a seat of influence and a source of contagion, and may affect other individuals not residing in his locality, and who see him only for a moment, and the result is developed within a well-known period of time. The history of other contagious diseases is similar, but there is no such history for scarlatina. We try to say that the cause is a peculiar, material, and easily transferable substance, of extraordinary adhesiveness and tenacity, so indestructible as to resist all ordinary means of cleanliness and purification (clinging to a bed-pan, for instance, fourteen months), not capable of entering the organism through the intact epidermis, and yet sometimes existing and developed in the child at birth; and that the contagion should operate in from four to seven days, and that when it does not this is because of a lack of individual susceptibility, which lack may enable a person to resist the contagion during a three months' residence in a close room with a patient having the disease severely, and may some months after be overcome on exposure to the clothing of the same patient in a healthy atmosphere in the country.

Is the sort of reasoning which such statements suggest the measure of the medical calibre of this day? Is it not wiser to concede that the pathogenesis of scarlatina is a mystery, as its whole history is irregular, inexplicable, and unreliable?

I do not oppose ventilation, and purification, and isolation during and after sickness, and especially with sickness where there may be so much fetid exhalation, but I object to an excited terrorism, which involves distress and anxiety, and cripples humanity.

Yours truly,

JOSEPH SARGENT.

WORCESTER, MASS., February, 1882.

### TRICHINOSIS.

In a recent instructive lecture on the subject of trichinosis M. Germain Sée distinguished four clinical types under which the symptoms may manifest themselves. The first is the gastro-intestinal form, in which the affected individuals are seized with grave

digestive troubles without apparent cause, epigastric discomfort and sense of distension, nausea, and vomiting. The times of the vomiting vary; sometimes they occur on the day on which the trichinous food was taken, sometimes they are delayed for four or five days. The vomiting is usually accompanied with diarrhoea, sometimes choleric form in character. Such symptoms, if slight, may be readily mistaken for a simple indigestion. If the nature of the disease is, however, suspected, the diagnosis may readily be made by the discovery of the entozoa in the stools. When the diarrhoea is excessive the symptoms may resemble those of cholera, but two distinctive characteristics are the excessive perspirations and considerable muscular prostration, which may even precede the onset of the diarrhoea. In the second, or rheumatoid, form, muscular pains are the dominant symptom; muscular exertion is painful, and causes fatigue. Towards the eighth day the muscles become swollen, hard and tender, and the flexors are always more affected than the extensors, and from the swelling of the muscles, shortening, and even a flexor contracture, may result. Painful trismus or difficult deglutition may be the effect of the presence of the trichinae in the muscles of the jaw and pharynx, and the affection of the laryngeal muscles may change the voice, and that of the intercostals

and diaphragm may cause a painful dyspnoea. With these are spontaneous pains, often severe, irregular in distribution, not corresponding to the course of the nerves, and constantly mistaken for rheumatism. In this form, also, there are usually initial gastro-intestinal troubles, which (as well as the prostration) should always arouse suspicion. The third and most characteristic is the oedematous form. The patients make their appearance with swollen faces, particularly the eyelids, and they complain of extreme prostration. The swelling may be bilateral or unilateral, and in the latter case is pathognomonic. This oedema, with normal heart and urine, with muscular prostration and initial gastro-intestinal troubles, should leave the diagnosis in little doubt. The last is the typhoid form, between which and enteric fever there are several analogies. There is continuous fever, considerable prostration, some dyspnoea, and much muscular pain. Three distinctive symptoms, however, are the profuse sweating, the oedema of the face, which is present in nine out of ten cases of trichinosis, and the brief duration of the pyrexia, which ceases although the other symptoms persist. The last is the gravest form, and death may occur in the second or third week with delirium or stupor, and the general aspect of a severe case of typhoid disease. — *Lancet*.

## REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 25, 1882.

Deaths reported 2619 (no reports from Philadelphia, New Orleans, and Cleveland): 1102 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 633, consumption 347, lung diseases 416, diphtheria and croup 165, scarlet fever 147, small-pox 91, typhoid fever 50, measles 44, diarrheal diseases 39, whooping-cough 26, cerebro-spinal meningitis 22, malarial fevers 20, puerperal fever 16, erysipelas 12, typhus fever one. From *typhoid fever*, Pittsburgh 15, Chicago seven, Boston five, Buffalo four, New York, St. Louis, and Lowell three each, Cincinnati and District of Columbia two each, Baltimore, Providence, Charleston, Lynn, Peabody, and Marblehead one each. From *measles*, New York 28, Chicago six, Brooklyn three, St. Louis and Buffalo two each, Cincinnati, Pittsburgh, and Milwaukee one each. From *diarrheal diseases*, New York 14, Brooklyn and Chicago five each, Baltimore three, District of Columbia and North Adams two each, St. Louis, Cincinnati, Pittsburgh, Milwaukee, New Haven, Charleston, Lowell, and Lynn one each. From *whooping-cough*, New York 10, Boston and Pittsburgh three each, St. Louis two, Brooklyn, Baltimore, Milwaukee, Nashville, Cambridge, Fall River, Chelsea, and Taunton one each. From *cerebro-spinal meningitis*, New York seven, Chicago, Pittsburgh, and Worcester two each, Boston, St. Louis, Cincinnati, Buffalo, Charleston, Fall River, New Bedford, Holyoke, and Weymouth one each. From *malarial fevers*, New York eight, St. Louis seven, Chicago, Baltimore, District of Columbia, Holyoke and Northampton one each. From *puerperal fever*, Buffalo three, Pittsburgh, Milwaukee, and Worcester two each, New York, Brooklyn, Chicago, St. Louis, Cincinnati, District of Columbia, and Providence one each. From *erysipelas*, New York five, Brooklyn and Chicago two each, Worcester, Fall River, and Northampton one each. From *typhus fever*, New York one.

One hundred and seven cases of small-pox were reported in Cincinnati, Pittsburgh 60, St. Louis 14, Baltimore nine, Brooklyn eight, Boston three, District of Columbia three, Buffalo two, and Milwaukee one; diphtheria 33 cases, scarlet fever six, ty-

phoid fever three in Boston; scarlet fever 21, and diphtheria three, in Milwaukee.

In 39 cities and towns of Massachusetts, with a population of 1,012,210 (population of the State 1,783,086), the total death-rate for the week was 22.96 against 19.85, and 20.16 for the previous two weeks.

For the week ending February 4th, in 173 German cities and towns, with an estimated population of 8,436,712, the death-rate was 26.2. Deaths reported 4244; under five 2039; pulmonary consumption 625, acute diseases of the respiratory organs 453, diphtheria and croup 254, diarrheal diseases 131, scarlet fever 95, whooping-cough 74, measles and roteln 50, typhoid fever 33, puerperal fever 26, small-pox (Frankfort-on-Older, Hanover, Essen two, Eupen) five, typhus fever (Thorn) three. The death-rates ranged from 14.2 in Metz to 37.7 in Krefeld; Königsberg 30.1; Breslau 28.7; Munich 3.7; Dresden 23.8; Berlin 24; Leipzig 23.7; Hamburg 24.5; Hanover 27.6; Bremen 17.2; Cologne 23.2; Frankfort-on-Main 18.3; Strasburg 33.1.

In the 28 English towns, with an estimated population of 8,455,308, for the week ending February 18th, the death-rate was 26.4. Deaths reported 4275; acute diseases of the respiratory organs 759 (London), diphtheria-cough 280, measles 138, scarlet fever 92, fever 49, diarrhoea 25, small-pox (London 17) 22, diphtheria 18. The death-rates ranged from 14 in Leicester to 35.3 in Blackburn; Bristol 20.9; Birmingham 22.6; Leeds 22.6; Sheffield 22.6; Liverpool 24.8; Manchester 28.2; London 29.3. In Edinburgh 21.1; Glasgow 28; Dublin 36.9.

For the week ending February 11th in the Swiss towns there were 44 deaths from acute diseases of the respiratory organs, pulmonary consumption 40, diphtheria and croup 10, whooping-cough and diarrheal diseases each seven, typhoid fever five, scarlet fever two, puerperal fever one. The death-rates were, Geneva 34.6; Zurich 30.4; Basle 22; Berne 27.6.

The meteorological record for the week ending February 25th, in Boston, was as follows:—

| Date.            | Barom-eter. | Thermom-eter. |          |          |            | Relative Humidity. |             |       |            | Direction of Wind. |             |            | Velocity of Wind. |             |            | State of Weather. <sup>1</sup> |             |                       | Rainfall.         |  |

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 25, 1882, TO MARCH 3, 1882.

POPE, BENJAMIN F., captain and assistant surgeon. Relieved from duty in Department of Dakota, and to report in person to the Surgeon-General for duty in his office. S. O. 42, A. G. O., February 21, 1882.

MOFFATT, PETER, captain and assistant surgeon. Relieved from duty at Camp Spokane, W. T., to proceed to Fort Conr d'Alene, Idaho, and relieve Assistant Surgeon Spencer from duty at that post. S. O. 20, Department of the Columbia, February 11, 1882.

COLLIGAN, E. T., captain and assistant surgeon. Assigned to duty at Fort Stanton, New Mexico, relieving Assistant Surgeon Newton. S. O. 40, Department of the Missouri, February 21, 1882.

SPENCER, WILLIAM G., captain and assistant surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month, to Division Headquarters, and

for an extension of four months to the Adjutant General of the army. S. O. 19, Department of the Columbia, February 10, 1882.

SPENCER, WILLIAM G., captain and assistant surgeon. Relieved from duty in Department of the Columbia, to proceed to New York city, and on arrival, report by letter to the Surgeon-General. S. O. 46, A. G. O., February 27, 1882.

ERRATA. — Page 175, line 27, instead of "Dr. Watson" read "Dr. Cullen." Page 176, line 8, add "alone;" line 21, for "antipyretic" read "antiphlogistic;" line 35, for "does not cause deafness" read "does not usually cause deafness;" line 38, for "South Carolina" read "Alabama."

MASSACHUSETTS COLLEGE OF PHARMACY. — The regular monthly pharmaceutical meeting of the College will be held at 7.30 P. M., on Tuesday, March 14, 1882, in the College Hall, No. 151 Washington Street. Stephen P. Sharples, Sugar Manufacturer and Assaying. Henry W. Lincoln, Ph. G., Pharmacy Laws, are they Desirable? All persons interested in pharmacy and collateral pursuits are invited to be present.

DR. B. F. DAVENPORT, Registrar.

TUMOR FORMATIONS IN ACUTE PELVIC INFLAMMATIONS.<sup>1</sup>

BY HALL CURTIS, M. D.

WHEN first the attention of physicians was called to acute inflammations of the tissues connecting and covering the pelvic viscera they decided that the peritonæum was the exclusive seat of these affections. Later investigators placed them in the cellular connective tissue underlying the peritonæum. In 1857 this prevailing theory was upset by the investigations of Bernutz, when again the pelvic peritonæum came to be generally considered as the sole offending, or rather offended, membrane. Still many writers cling to their old beliefs and theories. Among them Nonat, Aran, West, and Hewitt, for they describe minutely the distribution of the cellular tissue and its inflammation, referring now and then to the occasional coexisting peritoneal inflammation as a mere accessory, the main affection being confined to the areolar tissue. During the past two or three years the tide seems to be turning more and more strongly in the direction of the views expressed by them. Among the articles published bearing on this subject especially to be mentioned is one in the *Saint Bartholomew's Hospital Report on Perimetritis and Parametritis*, by Walter S. A. Griffith. Another is found in the *Edinburgh Medical Journal*, June, 1880, written by A. Macdonald, and a third on *Obscure Pelvic Abscess, with Remarks on the Differential Diagnosis between Pelvic Peritonitis and Pelvic Cellulitis*, by Paul F. Munné, in the *Archives of Medicine*, December, 1880.

The truth seems to be that both tissues are affected separately or together, at times the one more than the other. Occasionally the line of demarcation is easily defined, and diagnosis may be simple; at times impossible. When acute observers like Duncan and Emmet state they are unable to make at the bedside a diagnosis, and the latter says the difference is merely a theoretical one, we need not be surprised at our own indecision nor wonder why hospital records offer such apparent contradictions.

As Dr. Priestley puts it, in an article written in 1872, "They have in a great measure the same causes, approximately the same symptoms, and require to some extent the same treatment, while they are often associated together. One by contiguity may light up inflammation in the other, and they may pursue their respective course at the same time and in the same portion."

There can be no doubt that these inflammations are among the most important, as they are also the most frequent, of all diseases confined to woman. Unfortunately they are often misunderstood or entirely overlooked. The symptoms at times are obscure, the course of inflammation chronic, or at all events not sufficiently acute to turn the attention of the attendant in the proper direction. The patient is supposed to be suffering from general debility, from tuberculosis, from hysteria or nervous prostration, while a vaginal examination, the only means by which a more correct idea of the true condition of the patient could be formed, is not made.

One of the earliest contestants for cellulitis, or, as

he termed it, peritertiary phlegmon, was Nonat, in 1840. And it is interesting to see that the localities he asserted to be the chosen sites for cellulitic deposit are identically the same described by Macdonald in 1880, and proved by anatomical studies made by König, Schlesinger, and Spiegelberg.

Macdonald gives six localities for cellulitis, as follows: (1.) In front of the uterus. Here the peritonæum is reflected at a level as high as the internal os, leaving the cervix bare of peritonæum, and connected with the neck of bladder by a plentiful layer of loose vascular connective tissue.

I do not see how in this position the cellular tissue can be considered plentiful (unless in the sense of sufficient). It is really scanty, which accounts for the comparatively rare occurrence of ante-uterine cellulitis.

(2.) Peritonæum covers the whole of the uterus posteriorly, extending to a considerable extent over the upper part of the vagina, but is so altered in its relation to the organ at or about the level of internal os as to have a thick layer of subserous connective tissue.

(In this position the cellular tissue is especially loose, is capable of great distention, as is often seen in the low bulging tumors in the posterior wall of vagina.)

(3.) On each side of the uterus a space, triangular in shape, with apex at either Fallopian tube and base at reflection of the vagina on to the uterus, which is not covered with peritonæum, is rich in blood-vessels and connective tissue.

(4.) Lastly, between the layers of either broad ligament, particularly at the lower part of them, is much highly vascular connective tissue.

As Macdonald says, it will be observed that the situations in which such inflammation may take place, with exception of the top of the triangles by the side of the uterus, are *low down in the pelvis*. He states the *upward spread* of the inflammation is prevented by the firm and unyielding peritonæum, but I should rather attribute its *descent* to the fact that the cellular tissue becomes looser and more abundant the lower it lies in the pelvis, and also to the law of gravitation. The fact is, at all events, that pelvic cellulitis as a rule is low placed.

Of these localities the utero-vesical is the least frequently affected. Much more common are the phlegmons of the broad ligament, of the lateral and post-uterine cellular tissue. Again, the left side seems to be more generally affected, attributed to the fact that the sigmoid flexure and the rectum, with the accumulated feces, are more liable to determine a congestion on that side.

These attacks of cellulitis, low lying as already stated, clinging to the pelvic wall, following closely down the sides of the cervix, depressing the vaginal cul-de-sacs, and thus, as it were, shortening the cervix, are as a rule to be distinguished only by a vaginal examination, though at times a carefully made bimanual examination will define the upper limits of the thickening, expressed by Duncan as presenting extent rather than a great mass or thickening.

In looking over such of the records of the City Hospital for the past ten years as I could have access to, taking them in hand from the time when Dr. Sinclair made his contribution on pelvic peritonitis, published in the first report of the Hospital, I have found 74 cases reported as peritonitis, 15 as cellulitis, and 24 as pelvic abscess. This would lead us naturally to infer that cellulitis is by far the rarer of the two affections,

<sup>1</sup> Read before the Obstetrical Society of Boston, November 12, 1881.

but I think some latitude must be allowed here for the bias of the physician in attendance. Certainly, in looking over the records some of the cases seem to have been cellulitis rather than peritonitis. For instance, in one case inflammation was low seated, the *cervix shortened*, the effusion *extending to os uteri*.

In another, an indurated mass involving uterus and cervix, extending *nearly to edge of os*; two weeks later free and continuous discharge of pus.

In another the body of the uterus was fixed, forming a part of the solid mass in the pelvic cavity, from which the os seemed to protrude *in a nipple-like manner*.

Again. Above a *short cervix* is a hardness almost stony in character, the os, admitting finger, had a *ring-like feel*, hard and rigid.

Another, tubular, from outside thickening, its edges semicartilaginous.

Another, pelvic roof very hard, cervix almost obliterated.

In connection with our statement that these tumors are situated low down in the pelvis we may also quote or refer to an autopsy made by West bearing on this point, where the uterus was pushed up and to the right by eight ounces of pus in the cellular tissue to the left and back of the organ. *The upper part of the abscess reached one and one half inch above the level of the os uteri.*

A post-uterine tumor resulting from cellulitis is generally smaller than one depending on pelvic peritonitis. It flattens the posterior cul-de-sac, or may even bulge it downwards, at the same time prolapsing the posterior vaginal wall.

These cellular infiltrations or so-called phlegmons as a rule do not form tumors sufficiently extensive to be recognized by an abdominal examination alone. When a cellulitis offers the signs of a tumor readily felt through the abdomen, as in the extensive inflammations of the broad ligament, there is an accompanying peritonitis, and usually suppuration.

When the brunt of the inflammation falls upon the tissues situated in the broad ligament its possible area seems to be much more extensive than in the other para-cervical regions. As the inflammation as a rule is more intense, so its ravages are more marked. It may, and often does, extend, as proved by König, into the cellular tissue of the inguinal region, into the cellular tissue forming the sheaths of the psoas and iliacus muscles, and into the abdominal parietes, rising as high as the umbilicus, or, climbing the steps of the areolar network, mounts into the hypochondrium, as was seen in a case reported by me to this Society some three years since.

In these cases the peritoneum is always affected, and the resulting tumor is prominent and readily recognized by external examination.

Dr. Gräffths, in his very interesting paper, divides these inflammations into para-metritis inguinalis, transversalis, and psoas para-metritis, considering each of them separately and giving cases in point. His inguinalis, so often seen shortly after delivery or abortion, consists in a hardness, tenderness, and prominence along or rather above Poupart's ligament, with retraction of the corresponding thigh. This form he considers leads us to the more remote varieties of para-metritis, namely, to that in the transversalis fascia and muscle and in the psoas sheath.

When the broad ligament is thus affected the peritoneal inflammation marches with an equal step, whereby

the large exudation masses are formed, and suppuration, as a rule, follows. The temperature chart of suppurative cellulitis is remarkable for its daily remissions. High in the evening it may be low in the morning; at times normal, or even below the normal line in the morning, yet rising to 105° F. at night.

As the peritoneum occupies a higher plane in the pelvic cavity, so its inflammations naturally would take a higher level than those confined to the cellular tissue. Moreover, the well-known tendency of peritonitis to spread from coil to coil of intestine, fusing them together into a tumor-like mass, lets us readily understand why this affection should rise higher than a cellulitis proper, which as a rule spreads laterally.

Adhesive peritonitis, the most frequent of the peritoneal inflammations, does not always betray its presence by a tumor. Its favorite site is in Douglas pouch, where at times the uterus, or an ovary bound to the sacrum, forms the centre of a mass of adhesive peritonitis and a resulting tumor. When, however, the peritoneal inflammation spreads and the various viscera are matted together, a large tumor is formed, most readily detected by an external examination.

These tumors may also be enlarged by a secretion of serum or pus poured into the meshes and intervals lying between the effused lymph and intestinal masses. These larger peri-metric tumors *theoretically* are to be diagnosed by the resonance irregularly distributed of the intestinal coils confined in the general mass. Pelvic peritonitis, as recognized by the vagina, is only found behind the uterus, does not *encroach on the lower part of the cervix, nor usually shorten the vagina*. The tumor resulting from a post-uterine cellulitis is generally smaller and does not throw the uterus so forcibly forwards, but it, as already stated, *lies lower, depresses and flattens the posterior cul-de-sac*, and often *prolapses* the posterior wall of the vagina.

The aetiology of the inflammation also throws a distinguishing light on the two affections, for injuries or diseases of the upper part of the vagina and of the cervix are, as a rule, followed by inflammation of the cellular tissue, whereas lesions of the upper part of the uterus light up a peritoneal inflammation. Bernutz states that the spontaneous opening of these *peri-metric* purulent collections into the vagina has never been demonstrated, in his knowledge, by an autopsy. I think we may borrow this weapon from him to prove one point, and show the higher situation in the pelvis of peri-metric effusions.

## REPORT OF PROGRESS IN MATERIA MEDICA AND PHARMACY.<sup>1</sup>

BY WILLIAM F. BOLLES, M. D.

### HYOSCINE.

E. MERCK sent a communication to the British Pharmaceutical Conference upon this alkaloid and others of the solanaceae, covering ground which has been previously touched in these reports. The following is an abstract of his paper: Professor Ladenburg in continuing his researches upon the mydriatic alkaloids of the Solanaceae has definitely confirmed the ex-

<sup>1</sup> Pharmaceutical Journal and Transactions; American Journal of Pharmacy; New Remedies; The Pharmacist and Chemist; Chemist and Druggist; Journal de Pharmacie et de Chimie; Archiv der Pharmacie, etc.

istence of a second alkaloid in *Hyoscyamus niger*. The presence of this alkaloid was indeed suspected from the difference in the physiological action between the crystallized and amorphous hyoscyamine. Here L. calls the new alkaloid "hyoscine." It is isomeric with atropine and hyoscyamine, whilst, however, atropine and hyoscyamine split up into tropic acid and tropine, hyoscine yields as decomposition products tropic acid and pseudo tropine.

Professor Edelfsen has instituted a number of clinical trials of hyoscine which, so far as they have gone, have shown that in certain cases it exercises a more constant and surer action than atropine, and that it also possesses a soothing and soporific influence. Professor Edelfsen has obtained beneficial results from hyoscine in the treatment of whooping-cough, asthma, and epilepsy.

These trials, although not conclusive, serve to show that in the new alkaloid we possess a pure and trustworthy remedy. The hydriodate and hydrobromate have been prepared by Mr. Merck.

He gives the following synoptical account of the three mydriatic alkaloids and of their origin according to the new views.

(1.) Atropine occurs: (a) In *Atropa belladonna*, L. It is also known as "heavy atropine" and "atropine verum." (b) In *Datura stramonium*, L. Is "daturin verum" or "heavy daturine."

(2.) Hyoscyamine is found: (a) In *Hyoscyamus niger*, L. (b) In *Atropa belladonna*, L. So-called light "atropine." (c) In *Datura stramonium*. Known as "light daturine." (d) In *Duboisia myrapioides*. So-called duboisine.

(3.) Hyoscine; in *Hyoscyamus niger*.

#### EFFECT OF CULTIVATION UPON BELLADONNA.

Mr. A. W. Gerrard, having an opportunity of obtaining a considerable quantity of wild belladonna plants, has undertaken a comparative examination of the alkaloidal value of wild and cultivated specimens. The former grew upon a very poor limestone soil incapable of producing ordinary cultivated crops, but which seemed particularly adapted to this plant, as it grew in great luxuriance to the height of six feet. The age, according to his estimate, was three or four years. The cultivated drug was obtained from an herb garden with a chalk sub-soil and a foot of good loam; the plants were three or four feet high and three or four years old. The following is the result of his analysis:—

|        | Wild Plant.   | Cultivated Plant. |
|--------|---------------|-------------------|
| Root,  | .45 per cent. | .35 per cent.     |
| Stem,  | .11 per cent. | .07 per cent.     |
| Leaf,  | .58 per cent. | .40 per cent.     |
| Fruit, | .34 per cent. | .20 per cent.     |

There was a decidedly greater percentage of alkaloids in every part of the wild plant, although the cultivated specimen was considerably better than the average.

#### PETROLEUM OINTMENTS.

The melting points to which it is desirable to have our petroleum ointments adjusted have been carefully considered by numerous gentlemen, especially by several interested in the revision of the Pharmacopœia whose views probably foreshadow the requirement of a somewhat stiffer preparation than the ordinary vaseline or cosmoline as now sold. Both these preparations in the heat of midsummer become almost fluid and in-

stead of forming a consistent non-adhesive dressing are too apt to soak away indefinitely into the cotton.

The possession of two degrees of hardness in fatty dressings is a convenience that the surgeon would be loath to give up, and it is earnestly to be hoped that the Pharmacopœia Committee will give us two grades of petroleum "ointment" which shall correspond with the ointments and cerates of the present edition. Mr. Rice at the last meeting of the American Pharmaceutical Society read a paper upon the subject which may be surmised to be somewhat prophetic so far as the new Pharmacopœia is concerned. He quotes as the opinion of a number of physicians that he would like two of these salves, one melting at 40° C. or 104° F., the other at about 46° C. or about 115° F.;—figures that would appear to be perfectly satisfactory. Then rather curiously giving as a reason the danger of confusion he recommends that only *one* of these, and that the lowest, should be recognized, but why it should be more confusing than the present unguentum and ceratum it is difficult to see. If this is the final decision of the committee, physicians will still have to write for any variation from the standard ointment under the proprietary names which they were hoping to get rid of. The classical distinction between an ointment and a cerate which Mr. Rice handles so respectfully is practically obsolete, mercurial ointment; which is generally used by innuendo, is as stiff as most cerates, while zinc ointment, which is much softer, is never so employed. The melting points of cerates adapts them especially for summer use; and for mixture with various softening medicaments; while ointments serve better in the winter and for admixture with dry powders. It is to be hoped that both the hard and soft petroleum ointments will be recognized.

#### IGNATIA.

Although known in Europe as an article of commerce for nearly two centuries, and for many years one of the important sources of strychnia, but little is accurately known of the plant which produces it excepting that it is a climbing shrub, bearing a large, several-seeded fruit. This has been described and figured a number of times, but never so carefully as by Flückiger and Meyer within the past year in an elaborate article in the *Pharmaceutical Journal*. They received from Manilla four fruits, one dry and three others preserved in alcohol, in a perfectly satisfactory state. They were globose, twenty-five to twenty-nine centimetres in circumference, with a smooth, shining, green epidermis (unripe), and ten or twelve seeds (the commercial portion) imbedded in a soft pulp. There was no appearance of any dissepiment which the authors believed, with probable truth, had become converted into the soft parenchyme surrounding the seeds. Their description both of the gross and microscopic appearances is very minute and careful, and the article is illustrated by nearly twenty interesting drawings.

M. Planchon has also, during the year, published an elaborate series of studies upon other members of the *strychnos* genus, especially those employed in the various processes for making curare. In the first paper he compares the microscopical characters of five or six barks from different species, including *nux vomica* (false angustura) "hoang nan," m'bondon, and the species used in South America for making curare, with the result of finding a decided similarity of struc-

ture in them all. The woods were characterized by silky fibres and large lacunae, but seemed to be less constant in their resemblance to each other than the barks. In the second paper there is the general and now pretty accessible history and description of curare, with the following *résumé* of its varieties, etc. All the cures contain products of some species of *Strychnos*, which plays the important part, the other plants mixed with them being evidently accessories. This has been demonstrated by physiological experiments undertaken recently with the bark of American species of *Strychnos*, which show that the characteristic action of the poison can be referred to them alone.

In the actual state of our knowledge we can indicate pretty clearly four regions where curare is prepared, and for each of them mention a species of *Strychnos* which is used as a basis for its preparation. These are passing from east to west:—

(1.) The region of the upper Amazon or of the *Strychnos Castelnauana*, Wedd. It yields the curare of the Ticunas, Pebas, Yaguas, and Oregones.

(2.) The region of the upper Orinoco extending towards the Rio Negro, where the *Strychnos Gableri*, Planch., is met with, which yields the curare of the Moquiritaras and Piaros.

(3.) British Guiana, *Strychnos torifera*, Schomb., associated with *S. Schomburgkii*, Kl., and *S. cogens*, Benth., from whence comes the curare of the Macasis, Oreunas, etc.

(4.) The region of Upper French Guiana or of *Strychnos Crevauxii*, whence comes that of the Trios and Roucouyennes.

In several successive numbers M. Planchon gives all the information that can be obtained regarding these different cures, as to their origin and preparation, in support of the above conspectus.

#### CHINOLINE.

At a meeting of the Materia Medica Section of the International Medical Congress, Dr. Donath stated that the tartrate of chinoline in the proportion of 0.2 per cent. completely prevents the lactic fermentation of milk, decomposition of urine and gelatine, and the development of bacteria in artificial cultivating fluid, and that it is superior in antiseptic power to sodium salicylate, quinine, boric acid, salicylic acid, copper sulphate, and alcohol. Even in concentrated solution it does not precipitate albumen, and in the proportion of 0.1 per cent. it prevents the putrefaction of blood, and the curdling of milk. In the proportion of one per cent. it completely destroys the coagulability of the blood. Taken internally it lowers the temperature in fevers, is useful in periodic neuralgia, and is an excellent local antiseptic. The dose for adults is one or two grammes dissolved in equal parts of syrup and water.

Children take it easily. It is said not to cause any unpleasant after-effects, such as giddiness and timidity. A further communication on the subject from Dr. Donath appears in the current number of the *Berichte* (xiv., 1769), from which it appears that chinoline, even in considerable quantity, does not affect the alcoholic fermentation, and is remarkably inactive towards yeast cells, a property that, notwithstanding statements to the contrary by Liebig and others, appears to be shared by quinine. The author states that chinoline is never found as such in the urine after administration, and he thinks it probable that it appears there as pyridine

carbonate, which also would have an antiseptic action. As the fact that it has sometimes been alleged that chinoline derived from coal tar is not identical with that derived from the decomposition of quinine and cinchonine, points to possible variations in the substance supplied under that name, it may be useful to know that in the second paper in the *Berichte*, above referred to, Dr. Donath gives a series of reactions for testing its purity — *Pharm. Journ. and Trans.*

#### CINNAMIC ACID AS AN ANTISEPTIC.

The recent artificial production of this well-known substance at a much cheaper rate than it can be separated from the oils and balsams of which it forms a characteristic portion, renders its antiseptic claims worth noticing.

It is a beautiful crystalline solid, having a slight odor, varying according to the source from which it is made. It dissolves in one thousand parts of water, sixty-six of oil, and is more soluble in borax and phosphate of soda solutions, as well as in alcohol, ether, and chloroform. Dr. Barnes, following Dr. Fieck and others in point of time, has reported some experiments made with artificial cinnamic acid, of which the following are the most instructive: (1.) Two grains preserved four ounces of urine from decomposition for one month in a warm room; (2) the same quantity preserved four ounces of a solution of albumen in water for seventeen days; (3) half a grain to the ounce prevented the fermentation of a solution of malt for thirty-five days.

There is now no lack of antiseptics of considerable power, and additions to the number do not call forth any special enthusiasm, but they all have some drawbacks either of odor, irritability, or taste, while some, as is the case even with the now indispensable carbolic acid, are occasionally dangerously poisonous.

Cinnamic acid is said to be unirritating, and never poisonous, and deserves trial.

## Hospital Practice and Clinical Memoranda.

### MASSACHUSETTS GENERAL HOSPITAL.

#### CASES IN THE SERVICE OF DR. SHATTUCK.

REPORTED BY MR. FREDERIC W. TAYLOR.

#### CHRONIC BRIGHT'S DISEASE WITH DIABETES.

CASE 1. S. G., aged sixty-two, farmer, living in New Hampshire, is a very large man, usual weight three hundred and five pounds, had been accustomed to drink considerably. Always well till January, 1881, when he thought he caught cold; had slight cough and wheezing respiration; subsequently suffered from pain and a feeling of cold between the shoulders, also from sweating, especially at night, felt cold even in a warm room. Entered the hospital July 28th, complaining of persistence of the cold feeling, of loss of appetite, nausea, occasional vomiting of mucus, bowels regular but dejections slimy. He was given a diet of bread and milk, and once a day a pill containing small quantities of belladonna, nux vomica, and colocynth. He did not vomit after entering the hospital, though troubled by gaseous eructations and a feeling of oppression in upper abdomen. August 3d the urine was acid; of normal color; specific gravity 1023; sediment increased,

containing many hyaline and granular casts; albumen less than one quarter per cent.

He improved much, and, though still complaining of occasional chilly sensation in the back, was discharged August 29th; weight about two hundred and seventy-five pounds.

He returned October 15, 1881, saying that one week ago while at work out doors he caught cold; since then his sleep had been disturbed by loud wheezing respiration; he had a slight cough but little expectoration. Sibilant and sonorous râles were heard in both lungs; chest otherwise normal. Given syrup of squills, paregoric, and potassic iodide. Urine: color normal; acid; specific gravity 1026; albumen less than one quarter per cent.; sediment slightly increased, containing numerous casts, coarse and fine granular, hyaline, fatty, of various sizes, some convoluted.

October 20. Respiration easier and much less noisy. Urine: specific gravity 1020; albumen and sediment less than at last examination; in sediment a few casts and crystals of uric acid.

November 3d. Appetite poor; gaseous eructations; respiration loud, without râles. Urine: specific gravity 1023; albumen large trace; sugar; in the sediment crystals of uric acid, and numerous hyaline and granular casts. Squills, paregoric, and potassic iodide omitted.

R Carb. ligni . . . . . 5i.  
Potassii bitartratis . . . . . 5ss. M.  
Three times a day after meals.

R Tr. gent. co. 5ij. three times a day before meals.  
To eat no sugar or potatoes.

November 11th. Appetite not improved. Omit tr. gent. co. and potass. bitart.

R Potassii bicarb. gr. x. three times a day.

November 18th. Micturition less frequent, feels better. Ordered to drink no water but Vichy.

November 21st. Urine: slightly pale; acid; specific gravity 1020; albumen large trace; sugar 1.7 per cent.; sediment slight, containing uric acid crystals, and numerous hyaline and granular casts.

<sup>1</sup> Morning urine; the others are specimens of the twenty-four hours' urine mixed.

January 6, 1882. General condition good; goes out every day; would not think himself sick if he did not know that he had diabetes; complains that he does not relish food, yet he takes a large amount; drinks much milk and some Vichy water. Urine: acid; slightly pale; specific gravity 1022.5; albumen one quarter per cent.; sediment contains uric acid crystals, numerous hyaline and granular casts, some with round cells adherent.

#### DIABETES.

CASE II. December 1, 1880. Jane L., aged twenty-three, single, a domestic, born in Ireland, and has lived in Springfield. Well till five years ago, when she had "diphtheria and inflammation of the bowels." One year ago last month she had typhoid fever. Last February she worked very hard, was up much at night; has not been well since. At that time she first noticed thirst and a profuse and frequent micturition. Since then she has been in California, and has been losing strength and flesh continually. Six weeks ago her legs swelled, and she gave up work; has felt better since. At present appetite good; bowels regular; catamenia normal; temperature 99° F.; pulse 80. Urine: pale; specific gravity 1054; large amount of sugar. Nothing abnormal found in chest or abdomen. Best weight 145 pounds; present weight 122 pounds. Diet restricted to gluten bread, butter, meat, eggs, Vichy water.

December 8th. Less thirst; better appetite. Urine: acid; pale; specific gravity 1030; 89.788 grammes of urea in twenty-four hours; albumen very slight trace; sediment considerable; contains blood, leucocytes, and sugar spores. Complaints of gastric acidity.

R Sodii bicarb. gr. x. three times a day after meals.

December 17th. Thirst variable; drinks two quarts of Vichy water in the twenty-four hours; has a variety of bread.

December 29th. Weighs 112 pounds. Perspires after taking a warm bath. Is allowed milk and fish.

January 7, 1881. General condition good; takes an hour's walk each day; is in bed the rest of the time.

R Tr. opii m. x. three times a day.

R Fowler's solution gr. iij. three times a day.

February 4th. Omit sodii bicarb. and tr. opii.

R Potassii iodidi gr. x. three times a day.

February 14th. Decidedly improved some days; others worse. Omit Fowler's solution.

R Saponis gr. iv. three times a day.

R Morph. sulphatis gr.  $\frac{1}{2}$  three times a day.

March 11th. Omit present medicines. Feels as strong as ever. Pulse 84, full and strong.

R Sodii salicyl. . . . . gr. xij.

Tr. opii decod. . . . . m. x. M.

Three times a day.

March 20th. Increase salicylate of soda to gr. xx. three times a day.

March 26th. Failing. Return to a varied diet. Omit salicylate of soda.

R Acidi carbolici m. ij. three times a day.

April 1st. Ferri iodidi gr. i. three times a day.

April 13th. Food does not sit well. Omit carbolici acid. Takes four quarts of skimmed milk daily.

April 16th. Omit skimmed milk; return to restricted diet.

R Potassii iodidi gr. vi. three times a day.  
 R Morhiae sulphatis gr. ʒ three times a day.  
 R Saponis gr. ix. three times a day.

April 19th. Increase potassic iodide to gr. x.; later it was increased to gr. xx. three times a day.

April 29th. Sodii bicarb. ʒi. three times a day.

May 22d. Is tired of hospital, and wants to go home; will continue treatment there.

September 24th. Patient has been comfortably well most of the time since leaving the hospital; recently the amount of urine has diminished. She went to a party September 22d, taken sick at four p. m., September 23d, and died this morning at nine o'clock; symptoms of last sickness not learned.

#### CHRONIC BRIGHT'S DISEASE WITH RECOVERY.

CASE III. October 23, 1871. J. W. N., fisherman, aged thirty-six, born in Prince Edward's Island, and living in Provincetown. Family history good. Uses tobacco freely, and till within eight years liquor also. On the 10th of last September was up all one night, but well protected from exposure; on the 11th found his feet and ankles somewhat swollen, and on the 12th his legs and abdomen, and soon after his scrotum and penis; oedema and ascites have gradually increased; at one time much dyspnoea; has had no trouble with eyesight, no vomiting or headache; he is sure there has been no oedema of face; pulse 72; temperature 98.5° F.; appetite fair; thirst considerable; bowels free; estimates amount of urine one pint in twenty-four hours. Urine: acid; specific gravity 1018,  $\text{uph} + \text{u. cl. c. p.} -$ ; albumen considerable; hyaline, granular, and fatty casts.

Lies with three pillows under head; emaciation marked; abdomen not very large; no resonance from a few inches above umbilicus down; hepatic dullness begins just above fourth rib; right back dull at lower angle of scapula; crumpling at end of inspiration over lower right back; sounds of heart normal.

R Tr. ferri chloridi . . . . . gtt. x.  
 Three times a day.

October 27th. Vomiting; abdomen tense; feet much swollen; pulse 64, small, varies in strength; dyspnoea.

R Tr. aloë et myrrh . . . . . ʒss.

October 28th. Three loose dejections; feels better.

November 1st. Thinks he passed two pints of urine in twenty four hours.

R Ol. morrh. . . . . ʒss.  
 Twice a day.

November 14th. Legs and abdomen improved. Takes every day or two a pill of podophyllin and belladonna, by which bowels are kept loose.

November 27th. Left leg nearly normal in size.

R Liq. am. acet. . . . . ʒss.  
 Tr. scilla . . . . . ʒj.  
 Tr. digitalis . . . . . gtt. viii. M.  
 Three times a day.

December 25th. Omit liq. ammon. acet., digitalis, etc.

January 6, 1872. Urine same as at first examination.

January 10th. Much serum oozes from left leg. Puncture both with needle.

January 12th. Omit ol. morrh. and tr. ferri chloridi.

January 13th. Says he never felt better in his life.

January 16th. Urine same.

January 30th. Dullness over lower right back, sibilant and sonorous râles.

February 10th. Tr. ferri chlor., ten drops three times a day.

March 8th. Bandage leg.

March 19th. Urine: acid; specific gravity, 1025,  $\text{uph} + \text{u. n. cl. n. and c. p. n.}$ , albumen considerable; hyaline and fatty casts in abundance.

March 23d. Discharged much relieved. Laxatives taken all the time.

December 20, 1876. Reports that he is perfectly well, works regularly at bridge building, lifts heavy weights, and is exposed to wet and cold. Urine still contains casts and albumen.

January 16, 1878. Same as in 1876.

December 14, 1880. Urine: color normal; acid; specific gravity 1021;  $\text{uph. n. ind. sl. +, u. n. u. sl. +, cl. n. e. p. a. p.} -$ ; albumen slight trace. In sediment much calcic oxalate, blood, few leucocytes, hyaline and granular casts.

January 9, 1882. Still works at bridge building; is strong and well as any one. Urine: color normal; acid; specific gravity, 1021; albumen slight trace. In sediment an occasional blood globule, and doubtful granular cast.

#### CANCER OF HEAD OF PANCREAS AND OF THE LIVER.

CASE IV. Charles F., aged fifty-two, a musician, born in Germany, and living in Boston, entered the hospital August 18, 1881, and gave the following history:—

Family history good. Have been in the habit of using considerable wine and beer, also some distilled liquor, but seldom to intoxication. For the past six years I have had five or six loose dejections a day without pain. Four months ago skin and conjunctive became very yellow. I vomited, and feces were white; since then I have vomited occasionally, lost fifty-five pounds of flesh, and have some pain in right side of body generally. The yellowness of the skin varies in intensity frequently; feet and legs swollen at times; sleep disturbed by itching; appetite good, but food does not sit well on my stomach.

Physical examination. Bright yellow color of skin, conjunctiva, and mucous membrane of mouth; hepatic dullness not increased in area upward; below border of right ribs is felt a hard, oval mass, about the size of a lemon, which rises and falls with respiration, is dull on percussion, of the density of liver substance, and occupies the position of the gall-bladder. Urine

is of a dark, greenish-brown color, and contains much bile pigment.

September 22d. Patient is seldom in bed all day; goes out doors occasionally; has lost some flesh and strength since entrance; prominence below right ribs larger and more superficial; dejections dark gray, pul-taceous, and average four a day.

October 17th. Patient apparently improving; goes out every pleasant day; appetite better; no increase in size of tumor; urine nearly normal in color; dejections of a dark-slate color.

November 16th. Tumor no larger, but lower edge of liver readily felt; urine, color high, acid, specific gravity 1007, large trace of albumen; in the sediment a few granular and epithelial casts.

December 7th. Has been losing strength the past few weeks; some pain in right hypochondrium; dejections liquid.

December 22d. Is much weaker, and remains in bed all the time; defecation and micturition involuntary.

January 1, 1882. Apathetic; occasional severe pain in right hypochondrium; delirious at times.

January 4th. Pulse gradually failed till he died, at 11.15 A. M. Since the dejections became liquid the urine diminished greatly in quantity; for the last three weeks he passed but twelve or sixteen ounces a day; urine passed this morning was as follows: color dark; acid, specific gravity 1016, bile pigment, albumen large trace; in the sediment, renal epithelium, numerous granular and epithelial casts, little free blood.

January 5th. *Autopsy.* Universal yellow color not only of the surface of the body, but of all the tissues. Kidneys slightly enlarged; epithelial lining of the convoluted tubes granular, with an extensive deposit of amorphous biliary pigment in some of the cells. Intestines: mucous coat thickened, covered by a layer of mucus, the ends of the papilla of a dark-slate color. Liver large, its gall ducts greatly distended; scattered throughout its substance were numerous cancerous nodules, in size from a pin's head to a cherry; the liver substance itself was of a dark, greenish-yellow color, but otherwise normal. The gall-bladder and both cystic and common ducts were greatly distended, the latter easily admitted the thumb. The pancreas was large, dense, with lobules distinct, cancer in the head, and results of inflammation in the tail; the head evidently pressed upon the outlet of the common gall duct so as to obstruct the flow of the bile. The left pleura contained a few cancerous nodules.

#### HEPATIC CIRRHOSIS. DEATH FROM HÆMORRHAGE.

CASE V. Sarah D., aged thirty-three years, born in Canada, and living in Boston, entered the hospital November 9, 1880. Father died with an enlarged liver, mother of heart disease. Patient had intermittent fever eighteen years ago, pneumonia and pleurisy six years ago. Since having pneumonia she has had attacks of bloody dejections every two or three months, the attacks last three days, there are three or four dejections a day, each dejection containing half a cupful of blood. Epistaxis nearly every day for more than a year. One year ago she had an attack of vomiting and diarrhœa, which kept her in bed a week; she did not fully recover her health till five months afterward. Since some time last summer she has averaged four loose dejections a day; several days ago they were white, now nearly natural in color. Conjunctive have

been yellow for several months; the color has been more marked the past six or eight weeks. At present she complains of a dull pain in right hypochondrium, sharp pain in left hypochondrium and in left lumbar region, lassitude, imperfect sleep.

Catamenia have always been irregular, the interval between them varying, and always being longer than a month.

Physical examination. Complexion is dark, with a decided yellow color, which is especially noticeable on chest and abdomen; no emaciation; area of hepatic dullness normal; liver cannot be felt beneath the border of the ribs; area of splenic dullness much increased; heart not enlarged, soft systolic souffle at the apex; slight general tenderness of the abdomen; urine acid, specific gravity 1005, bile pigments present, albumen absent, nothing abnormal in the sediment.

November 19th. Frequent bloody dejections the last few days; blood enough in some of the dejections to form a clot several inches in diameter on the bottom of the vessel; emesis this morning; vomitus green.

December 6th. Abdominal pain; dejections dark; feet œdematous; liver can be felt beneath border of ribs at the end of a deep inspiration.

December 13th. Legs and face œdematous; urine dark; patient remains in bed.

December 21st. Two boils on neck bleed very readily; epistaxis frequent; in the evening epistaxis from right nostril, which did not stop till both anterior nares were plugged; about one pint of blood was lost; it clotted very slowly. Ext. ergotæ fl., ten minims, every two hours, were then given.

December 22d. Slight flowing; three dejections last night, and four to-day; they consisted almost entirely of blood; at eight P. M. hæmorrhage from the posterior nares; stopped only by plugging.

December 23d. No loss of blood except slight flowing; ergot omitted; during the day took a few ounces of milk and stimulants; became unconscious at three P. M., and died at 9.30 P. M. There was a slight rise of temperature just before death.

December 24th. *Autopsy.* Spleen much enlarged. Recent hæmorrhage in the mucous membrane of the pelvis of one kidney. Mucous membrane of the stomach and of the intestines was besmeared with a dark-red, almost black, viscid material, showing red in dilution; mucous membrane of ileum was stained with a dirty red color. The liver weighed three pounds, fourteen ounces, avoirdupois; their surface was irregular and lobulated, the largest elevations being not more than one half inch in diameter; the organ was dense, and symmetrically atrophied; on section the lobules were seen to consist of islets of unaltered parenchyma separated by streaks of connective tissue; the entire liver was of a greenish-brown color. The gall-bladder was shrunken to the size and shape of a little finger, and contained a white cylindrical calculus, one and one half inches long. The cystic duct near the gall-bladder contained three small white calculi. The lymph glands in the immediate vicinity of the liver were swollen and soft, on section gummy, resembling dregs of paint.

—The *Medical Press and Circular* records the death, from diphtheria, caught during the performance of tracheotomy, of Dr. Gadshy, of Mansfield, Nottinghamshire, at the early age of twenty-eight.

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

FEBRUARY 27, 1882. DR. W. STURGIS BIGELOW made some remarks on the study of bacteria and their relations to disease, to the following effect:—

#### THE STUDY OF BACTERIA AND THEIR RELATIONS TO DISEASE.

DR. BIGELOW said: The nature and characteristics of the lower organisms, and their relation to disease, is a subject which has of late attracted so much attention both in this country and in Europe that it has become more or less familiar to every one in the form in which it is presented in the medical journals. Unfortunately, however, most of the articles in the journals presuppose on the part of the reader a familiarity with certain general facts connected with the subject which he does not always have the time or opportunity to acquire. Hence it often results that a man may become thoroughly acquainted, on paper, with the minute details of some hairsplitting controversy as to whether a certain bacterium has or has not a constriction in the middle or a flagellum on the end, without having himself ever seen a bacterium; or with a rigid and closely-reasoned criticism of experimental methods, without knowing either the essentials of a good experiment or the commonest faults of a bad one.

DR. B. did not propose to go into details still *sub judice*, but to speak of a few general points connected with the natural history and classification of the microbia, with the methods of experiment, and with their relation to disease where such relation has been demonstrated.

The floating dust in the air consists of a certain quantity of amorphous matter together with certain well marked objects. The nature of the latter can be roughly predicted from the locality. Among them are filaments of animal and vegetable fibre from clothing, shreds of woody tissue, particles of mineral and other crystalline substances, fragments of the horny or siliceous layers of grains and grasses, and the spores or germs of the microbia.

These latter are very small, usually round or oval, with sharp outlines, and highly refracting or opaque. When sown in a suitable soil they grow like any other seed, giving rise to different organisms. Among these are the microscopic fungi and a series of organisms varying in form from a small sphere to a short oval, a long oval, or a more or less attenuated rod. They may or may not have motion, and in some cases flagella can be shown. They may be single, in pairs, or in chains. The chains are sometimes spiral, and some spiral forms occur apparently consisting of a single element, as if a rod were twisted into a corkscrew. In some cases colonies of organisms are clumped together in a mass of jelly—the zooglia. The number of forms appears to be unlimited. But the form, whatever it be, is constant in successive generations. The rods do not beget spheres, nor *vice versa*. But the spore of a large rod may be a small oval body, formed at a certain part of the rod.

A confusion of ideas has arisen from the use of the term "germ theory of disease." An organism which

causes a disease may be said, more or less figuratively, to be the germ of that disease, but the germ of a disease is a very different thing from the germ of an organism. All microbia, so far as known, possess one form in which they are permanent; in some cases, especially among the round or oval microbia, this form is not distinguishable from the form of the adult organism except by its higher refracting power, in others, as in bacillus of anthrax, the spores are glistening, oval bodies, one of which is formed in each end of the individual bacilli; after their formation the body of the bacillus dissolves, and the spores are freed.

No morphological classification yet made is satisfactory, from the constant occurrence of intermediate forms between the groups, no matter where the line be drawn.

A division on physiological lines is more satisfactory. Pa-teur distinguishes aerobia, which require oxygen to live, and anaerobia, which do not. A division into pathogenic and non-pathogenic is also made, though it is a question whether this will always hold good. The growth of different forms in organic fluids, part of whose chemical constituents are assimilated by the growing organism, causes chemical alterations in these fluids which constitute fermentations or decompositions. Hence organic fluids alter when exposed to the air, from germs falling into them and developing. If the germs be kept out, and the fluid contain none to begin with, it can be kept indefinitely in contact with the air without fermentation or putrefaction. Different organisms produce different changes in the same fluid. But the same organism always causes the same change under the same conditions. All organisms do not grow equally well in all fluids. The bacteria and micrococci grow best in alkaline fluids. The lower fungi in acid solutions.

To collect dust for examination several different methods have been proposed. If a current of air be drawn by means of an aspirator through a tube containing a plug of cotton wool, the dust will be arrested by the plug; and if for ordinary cotton gun-cotton be substituted, it can be afterwards dissolved in ether, and the spores collected by evaporating the ether. This method is open to the objection that immersion in ether may impair or destroy the vitality of certain spores. Besides, if a small quantity of ether be used, its evaporation leaves the spores imbedded in collodion, and in an awkward condition for future study, while if enough ether be used to dilute the collodion to a point where it ceases to interfere with the experiment, the spores are lost in the volume of fluid.

Another method is that employed at the Observatory of Mont Souris; a current of air produced as before by an aspirator is directed through a small tube vertically downwards against a drop of glycerine on a microscope slide; the objections to this are three: first, a certain amount of dust is carried away without ever touching the glycerine; second, the glycerine absorbs water from the air and the drop swells to an unmanageable size; thirdly, a spore in a mixture of glycerine and water is very disadvantageously placed for future study. A third method is that described by Koch, which is unquestionably the best. At the bottom of a beaker glass, eight inches deep, is placed a shallow vessel containing a fluid capable of supporting the microbia, mixed with two to three per cent. of gelatine, enough to render the mixture solid at common temperatures. The depth of the glass insures a quiet atmos-

phere inside it, and any germ which falls into the glass settles by its own weight till it falls on the surface of the gelatine; here it develops. In other words, the seed grows to a plant at the point where it falls, and the different species remain as separate and distinct as the different plants in a flower bed, and can be cultivated indefinitely by successive transplantations to fresh surfaces of gelatine.

It has been maintained by Nagele that all known forms of microbes were the modifications of two primitive types; later observers have, however, demonstrated the incorrectness of this view. Each form reproduces itself and nothing else, and assertions to the contrary are based on the errors of experimentation.

In regard to experimental processes it is well to bear in mind one or two general principles, which are best illustrated by an example. If an organic fluid such as blood be left for a few days exposed to the air, it will be found swarming with organisms of different species. Suppose we desire to study the effect of inoculating one of these species on an animal, how are we to isolate it? Until very lately, these experiments having been entirely performed with fluids, it was customary to attempt, by a series of transplantations in fluids, to try to kill off all the species but one. This was always a long and difficult process, for while certain general lines can be drawn, as, for example, between acid and alkaline fluids, yet it may be said to be a matter of chance if the experimenter stumbles on a fluid which will support only the particular organism he is studying. Another method is that suggested by Lister, who begins by making with the microscope an approximate estimate of the number of organisms in a given volume of fluid, and by a succession of dilutions, as in the homœopathic preparation of drugs, increases the volume of fluid to the point where each drop should contain by calculation a single organism. He then sows one drop of the diluted fluid in each of a large number of flasks containing sterilized infusions, and in a certain percentage of the lot he obtains the pure culture sought for; the method is an awkward and difficult one, and not to be compared for neatness, accuracy, and economy of time and work to the method of Koch's before spoken of.

In regard to the sterilization of instruments and fluids, processes which are common to all experiments, one or two general rules may be laid down. It should be remembered first that the spores show enormously greater powers of resistance to the effect of the changes of temperature or the action of chemical reagents than the organisms themselves, and that some of them will bear heating far above the boiling point of water, and for a considerable length of time, without losing their power of germination; it should be remembered also that these spores are deposited in immense quantities on the surfaces of all solid objects, and that no water except spring water taken at the spring itself is free from them, not even the distilled water of our laboratories. All solid objects, therefore, used in experiments must be thoroughly disinfected beforehand; in practice this is effected by heating them to a point which insures the partial or complete burning of the organisms. Acid fluids can be sterilized by heating to 100° C. for twenty minutes, neutral and alkaline fluids require heating to 110° C. for the same time. In a recent publication from the Health Office in Berlin, Koch describes some experiments of his own in which he reaches the remarkable conclusion that all organ-

isms, moist or dry, adults or spores, in acid or alkaline fluids, are equally killed by being heated for ten minutes to 100° C., and that the reason that previous experimenters have reached different conclusions is because their experiments have been so conducted that the organisms were not really heated to this point. To demonstrate this, a flask, capacity of one litre, was filled with water, and a maximum thermometer run through the cork so that its bulb came in the centre of the flask. The flask was then inclosed in a metal steam box, and heat applied. In the course of half an hour the steam reached 127° C., while the quicksilver of the thermometer in the flask had not reached 65° C., the lowest graduation on the scale.

These experiments have not as yet been repeated by other observers.

The ordinary methods of microscopic examination are insufficient to distinguish the slight structural differences between many forms of microscopic organisms. Staining of some sort is absolutely essential, and can be preferably done with aniline colors. Methylene blue is recommended by Koch for general use, but different organisms vary widely in their susceptibility to the action of any given color. To distinguish some of the finest points of difference a first rate sub-stage condenser, such as that made by Zeiss and known as the Abbé illuminating apparatus, is essential; without some such apparatus many organisms cannot be recognized, for example, that which causes septicæmia in mice, a rod so minute that countless numbers of them are found packed in the interior of a single white blood corpuscle.

Two points of general interest remain to be spoken of: the first of these is the now celebrated theory of cumulative virulence, originally announced by Davaine. This, in its present form, seems to be based largely on misunderstanding of the author's statement, which has been quoted from book to book, apparently without any one having taken the trouble to verify it by reference to the original paper. It was, briefly, as follows:

If a rabbit be inoculated with a decomposing fluid, such as blood, containing many kinds of microbes, several grammes are necessary to produce disease; but if a second rabbit be inoculated from the blood of the first a small fraction of a drop is sufficient, a third inoculated from the second needs still less, until the tenth rabbit dies on inoculation with the one trillionth part of a drop. It has been asserted that the activity of the virus increased in a regular proportion from the first rabbit to the last. This is not true, nor did Davaine ever say this; his own experiments prove that the virus is fatal in infinitesimal doses after the second rabbit, in other words, after a pure culture is obtained in the body of the animal, and its blood becomes crowded exclusively with an organism which existed but sparsely in the original solution.

The second point relates to the subject of vaccination; the principle involved being that an organism cultivated outside of the body may become, by a combination of circumstances controlled by the experimenter, so enfeebled in virulence as to produce its characteristic disease in a form which is not fatal. This effect Pasteur has described as being produced by the prolonged exposure of the microbes to the oxygen of the air. This result was first described by him in the case of chicken cholera, and subsequently in the case of charbon. Doubts have lately been raised in Germany in regard to the reliability of these vaccinations,

but in the meanwhile Pasteur has gone on vaccinating sheep and cows by the ten thousand, both in France and Hungary, and, so far, with triumphant success.

The speaker did not propose to enter on details of the vexed question of the diseases attributed to the presence of microbes, but referred his hearers to the work on traumatic infectious diseases by Dr. Koch, translated by the Sydenham Society. He added that the conditions laid down by this writer, to be fulfilled before any disease can be said to be caused by a given microbium, should never be lost sight of. First, that the microbium should be a well-marked and easily distinguishable form. Second, that it should occur in every case of the disease. Third, that it should occur in such number and distribution as to account for all the symptoms. Fourth, where inoculation is possible, it should produce the disease by inoculation on a healthy animal. The speaker showed the method of carrying out pure cultures on solids, and showed some characteristic forms of organisms under the microscope.

DR. MORRILL WYMAN said that his brother, the late Prof. Jeffries Wyman, had considered the influence of heated, dry, and moist air, steam, and also the influence of high pressure steam, five atmospheres about 300° F., upon living organisms. The boiling was continued four hours and yet the spores became productive; those under pressure were boiled fifteen minutes, and some of them became productive. He is very careful to say, in the published account, that these experiments are made without any reference to spontaneous generation. A flask which bears the mark "1867 June" still continues free from any evidence of organisms.

DR. CABOT asked Dr. Bigelow whether he would not expect to find the bacteria of diphtheria below the deposit rather than above.

DR. BIGELOW answered that he would, and that he should look for them especially on the edge of the process.

In answer to a question by Dr. G. B. Shattuck, DR. BIGELOW said that he regarded the *Spirillum of Relapsing Fever* as a well recognized organism and its relation to the disease as well established.

DR. ABBOT spoke of the alleged facts presented by Dr. Gregg in the *Medical Record* of February 11th, to the effect that the bacteria said to exist in diphtheria, etc., are only forms of fibrin granules, fibres formed from them, and spiral forms, such as these always take in coagulating fibrin, and occurring also in all inflammatory processes; the granules also being said to appear in some morbid processes from the disintegration of tissues, becoming putrid and leading to suppurations or putrid ulcerations, and possibly to septicæmia, but never forming false membranes.

DR. G. B. SHATTUCK referred to the conclusions of Drs. Wood and Formad as expressed in their recent report to the National Board of Health on the Nature of Diphtheria. Though acknowledging the presence of micrococci they do not find that these present any specific character; the micrococcus of diphtheria they consider identical with the organism found in health, though in a more active state and making a more successful invasion of the parts owing to local and atmospheric conditions.

#### RUPTURE OF MENINGEAL ARTERY.

DR. WHITNEY reported a case of rupture of the meningeal artery in a boy from the blow of a brick on the head, and exhibited the specimen.

#### UTERINE POLYPUS.

DR. MINOT showed the specimen, which was removed at the Massachusetts General Hospital from a woman, thirty-five years old, whose last child was born six years ago. For about eighteen months she had had menorrhagia, which became profuse and constant. The patient was blanched, feeble, and emaciated, but not confined to her bed. On examination, the vagina was found to be filled with a large tumor which was connected with the interior of the uterus by a stalk of the thickness of the little finger. The tumor was drawn down outside the vulva and the pedicle severed with scissors. The tumor was roundish, weighed four and one half ounces, and measured seven and one quarter inches in its longest circumference and six and three quarters in its shortest. It was of the ordinary fibroid character. No hemorrhage followed its removal, and the woman was discharged well, in a few days.

#### UNPLEASANT RESULTS FROM THE USE OF IODOFORM.

DR. FIFIELD wished to present to the attention of the Society a case which had caused him much anxiety from the surprising effects produced by the cautious application of a small quantity of iodoform in powder to some ulcerated surfaces. In view of the great and constantly increasing use of iodoform, both in the hospitals of Europe and in this country, he deemed the subject worthy of much careful study, and thought that as the substance had been spoken of as a rival, and in some respects the superior, of carbolic acid as an antiseptic, its possible dangers as well as its good effects should be made known as quickly as may be. Dr. Fifield then alluded to the two fatal cases at Breslau where iodoform had been largely and successfully used in the treatment of caries. The history of these cases showed death to have resulted in one case in two days, in a second in sixteen days. In both there was intermittent drowsiness ending in coma, paralysis of sphincters, aphonic disturbance of speech, contraction of the muscles of the neck, and scaphoid retraction of the abdominal walls, together with great frequency of pulse from the beginning. Temperature normal. In the second case the patient continued in good condition for nine days during the use of iodoform (externally), then headache, and somnolence for two days. Fatty degeneration of the heart with cloudiness of the liver and kidneys were shown post mortem.

Dr. Fifield's case was as follows:—

A young lady had had for some time cethymatous ulcerations with typical, piled-up, oyster-shell-like scabs in different parts of the body, particularly affecting the scalp, which was the seat of numerous foul ulcerations threatening the very bones beneath. On Friday last, at very urgent solicitations of relatives that some vigorous effort be made to arrest the progress of the disease which had obstinately refused to yield to mercurials and iodides in all forms, Dr. Fifield had removed certain scabs on the hands and one scab on the left temple, and had sprinkled them with iodoform. On Saturday, no unpleasant result having been experienced, the scabs of three other ulcers of the scalp had been removed and their surface lightly strewn with the same powder. On Saturday afternoon he was surprised to find the patient with swollen scalp, profuse serous discharge from nearly its whole surface, which presented a typical acute eczema. No constitutional effects complained of.

On Monday head and face enormously swollen, eyelids puffed out to a degree interfering with vision. Neck somewhat swollen on right side with tendency to contraction of muscles, profuse serous and purulent discharge from scalp, soaking the pillow on which the head rested. A powerful odor of iodoform filled the house. At noon the same day the eyelids were less swollen, the neck rather more.

Tuesday, 28th, swelling subsiding. Some little nausea complained of; had not rested well; pulse rather quick; temperature normal.

March 1st. All alarming symptoms have disappeared.

Dr. WEST, in answer to Dr. Fifield, said that Professor Billroth used iodoform very freely in the treatment of wounds, and out of hundreds of cases which he had seen treated in this way he had never seen a case of poisoning. The cases of poisoning were where cavities had been filled with iodoform.

Dr. H. J. BIGELOW, referring to the use of iodoform in his wards, said that in certain subjects it acted as a local irritant, and in this way might cause trouble.

Dr. C. H. WILLIAMS said that he had treated an ulcerated eyelid with iodoform freely applied and without bad result.

Dr. FITZ spoke of the necessity of preliminary cleanliness, as insisted upon by German authors, before applying the iodoform.

## PROCEEDINGS OF THE MEDICO-LEGAL SOCIETY OF NEW YORK.

REASONING MANIA; ITS MEDICAL AND MEDICO-LEGAL RELATIONS, WITH SPECIAL REFERENCE TO THE CASE OF CHARLES J. GUTEAU.

ONE hundred and seventy-ninth meeting, MARCH 1, 1882.

A large audience assembled to listen to the paper of Dr. WM. A. HAMMOND on the above subject and the interesting discussion which followed it. The first authority to differentiate this form of mental disorder, the writer said, was Pinel, who published an account of it under the designation, *Mania without Delirium*, in which he summed up his description as follows: "It may be continuous or characterized by the occurrence of periodical accessions. There is no marked change in the functions of the understanding, the perception, the judgment, the imagination, the memory, etc., but perversion of the emotional faculties, and blind impulses to the perpetration of acts of violence, or of even sanguinary fury, without its being possible to recognize the existence of any dominant idea or any illusion of the imagination to which the acts in question can be ascribed." Since that time a more definite conception of the affection had been entertained by leading alienists of every country, and he quoted from the writings of Esquirol, Morel, and Dagonet, as well as of Pinel. Among the English authorities who recognized reasoning mania as a distinct affection were Prichard, Maudsley, Bucknill, and Conolly, and among the Germans were Hoffbauer, Griesinger, and Caspar, while in America, the late Dr. Isaac Ray was the most distinguished advocate of its claims.

In describing more fully the affection as it had been portrayed by others, and as he had observed it in his own experience, Dr. Hammond mentioned that its

most prominent characteristic was an overbearing egotism, which constantly showed itself, even on the most unimportant occasions. Though without social position, wealth, or political influence, the individual conceived that he had only to make his wishes known to those in authority in order to have them granted, and he would not hesitate to push himself forward as an applicant for high office in spite of numberless refusals and the most pointed rebuffs, although he might not possess a single qualification for the position he was seeking. Any little act of common politeness that might be shown him was construed at once into a promise of assistance, and he was always sanguine of success in his projects. When, however, the inevitable disappointment came, his chagrin was of short duration, and, conoling himself with some plausible excuse for his failure, he would soon begin to direct his energies to the securing of some other and perhaps still more unattainable position. In illustration of this point, the writer described in detail the case of a young man affected thus, who had recently been under his care. Convinced that he was entitled to a position as a sort of commissioner of emigration for the United States in Europe, he had gone on to Washington to obtain an interview with the President, and his father had only been able to get him home again by calling in the assistance of the police.

The intense egotism of these persons made them utterly regardless of the feelings and rights of others, so that everybody and everything had to give way to them, and their comfort and convenience had to be secured although every one else was made uncomfortable or unhappy. Another manifestation of their intense personality was their entire lack of appreciation of any kindness done them. All benefits conferred upon them were regarded by them as so many rights to which they were justly entitled, and hence they were apt to be ungrateful, arrogant, insolent, and abusive to those who had served them, and shamelessly hardened in all their conduct toward them. At the same time, if advantages were yet to be gained, they were sycophantic to nauseousness in their deportment toward those from whom the favors were expected. While boasting of their genius, their piety, their high sense of honor, their learning, and other qualities and acquirements, they were perfectly well aware that they were, in reality, commonplace, irreligious, cruel, vindictive, utterly devoid of every chivalrous feeling, and saturated with ignorance. It was no uncommon thing for the reasoning maniac, influenced by his supreme egotism and desire for notoriety, to attempt the part of a reformer, and in doing this he generally selected some practice or custom in which there was really no abuse. His energy and the logical manner in which he presented his views, based, as they often were, on cases and statistics, imposed on many worthy people, who eagerly adopted him as a genuine champion of morality and overthrower of vicious practices. But sensible persons soon perceived that there was no sincerity in his conduct, that he cared nothing whatever for the cause he was advocating, and that his cases and statistics were forged, or intentionally misconstrued for the direct purpose of deceiving; in short, that the philanthropy or morality which he affected was assumed for the occasion. Even when his hypocrisy and falsehood were exposed he continued his attempts at imposition, and even when the strong arm of the law was laid upon him he would prate of the ingratitude of those

he was endeavoring to assist, and of the disinterestedness and purity of his own motives. Dr. Hammond then dwelt for some time on the cases of two noted criminals whom he regarded as subjects of reasoning mania, William Speirs, who attempted to burn the State Lunatic Asylum at Utica in 1857, and Hélène Jégado, the French poisoner, who destroyed no less than twenty-eight lives between 1853 and 1857. Jesse Pomeroy and other similar monsters he also believed to come under this category.

He next took up the question of derangement of the intellect in this affection, and stated that he was quite sure that though the emotions and the will were primarily and chiefly involved there was more or less aberration of the purely intellectual faculties in every case. There could be no doubt whatever that this had been so in every instance that had come under his personal observation. On a superficial examination the intellect might appear to be unaffected, as it very generally happened that there was an absence of marked delusion; but a ready susceptibility to be impressed by slight exciting causes, an unquestioning faith in their own powers (when in reality these were far below the average), and an entire disregard of their duties and obligations, and of the ordinary proprieties of life, could not, in his opinion, but be regarded as indications of intellectual derangement. Most authors who had described the affection appeared to think that it invariably existed without the participation of the intellect; while others, perceiving that the intellect participates to some extent in all cases of mental derangement, refused to admit the existence of such a thing as reasoning mania. The question was a mere quibble, however, for whether the intellect was involved or not was by no means a matter of prime importance.

Dr. Hammond then went on to speak of the case of Guiteau. It was scarcely necessary to go over the whole record of the trial, he said, in order to form a definite opinion of the man's mental condition. We had only to take the hypothetical question proposed by the District Attorney, and which was answered by every one of the medical witnesses for the prosecution in positive language, that if the statements therein contained were true, the prisoner was sane. He went briefly over the statements referred to, which comprised an outline of Guiteau's life and conduct from the time he entered college to the date of the shooting of President Garfield; and then proceeded to say that on such a statement of facts, and with a knowledge of the manner in which the prisoner conducted himself while being tried for his life, his abuse of his friends who were trying to save him, his praise of judge, jury, and opposing counsel at one time, and his fierce denunciation of them at another, his speech in his defense, his entire lack of appreciation of the circumstances surrounding him, his evident misapprehension of the feelings of the people toward him, his belief in the intercession of prominent persons in his behalf and of his eventual triumph, and the many other indications with which all were familiar, — especially his conduct after his conviction, — he had no hesitation in asserting that Guiteau was the subject of reasoning mania, and hence a lunatic. What, then, was to be done with such persons as Speirs, the Utica incendiary, Brown, the Maine wife-murderer, Jégado, the poisoner, Dumolard, the killer of servant girls, Pomeroy, the boy-torturer, and Guiteau, the assassin of the President? That all these people were lunatics he had no doubt;

that all fully deserved the punishment awarded them he was quite sure. It was a source of satisfaction to him, he continued, to find that the views which for nearly ten years past he had endeavored to promulgate had at last received practical indorsement by the conviction of Guiteau. The charge of Judge Cox showed what he thought; and it was doubtless due to his very emphatic declaration that insanity, unless of such an extent as to destroy the knowledge of right and wrong, or prevent the accused knowing the nature and consequences of his act, did not absolve from responsibility for crime, that a verdict of guilty was rendered. The charge of Chief Justice Davis, of the New York Supreme Court, in the recent Coleman case, was also commended in this connection. In it he said, "Emotional insanity, impulsive insanity, insanity of the will, or of the moral sense, all vanish into thin air whenever it appears that the accused party knew the difference between right and wrong at the time and in respect of the act which he committed." Dr. Hammond concluded as follows: "As I have endeavored to show quite recently, there is no necessary connection between medical insanity and legal insanity. Let Guiteau suffer the full legal penalty for his crime; but let him be executed with the distinct understanding that he is a lunatic deserving of punishment. To shut our eyes to his exact condition, and to try to flatter ourselves that he was of normally constituted mind when he shot the President, is not only cowardly, but it is impolitic. The conviction and execution will be without the force of an example upon hundreds of others of unsound minds who may be contemplating the commission of crimes; and it will lead to the erroneous conclusion that there was a sane man, a man in the full possession of his mental faculties, capable of killing the President of the United States for the purpose of uniting the two wings of the Republican party, when both had never failed to show their contempt for the assassin whenever he had given them the opportunity. Was there ever a more insane motive than this, and was there ever a man whose whole career from childhood to the present day has afforded a more striking example of the form of mental derangement called reasoning mania?"

In the discussion which followed the reading of the paper Dr. RALPH L. PARSONS was the first speaker. He coincided fully with the views of Dr. Hammond as to the existence and nature of reasoning mania, but could not agree with the latter as to the legal punishment of such cases. He held that the criminal insane should be treated as a class by themselves, and that the verdict of the jury in this class of cases should be a special one. He did not at all coincide with writers who were of the opinion that the insane did not reason and were not actuated by motives; but the reasoning was insane in its character, and the motives those of madness. It was said that these cases ought to be punished for the sake of example; but the sane were not influenced by such examples, and the poor insane who might be cognizant of the punishment would not be affected unless it were brought directly to their knowledge. For the protection of society, however, criminals of unsound mind should be permanently confined in a proper house of detention for the insane.

MR. GEORGE H. YEAMAN questioned the value of the term "reasoning mania," as tending to complicate the nomenclature of insanity; but agreed with the au-

thor of the paper as to the propriety of holding Guiteau legally responsible for his crime.

Dr. E. C. SPITZKA said that in his examination he had found Guiteau full of delusions. His egotism and assurance were wonderful, and when he came to mount the scaffold it would be with the firm belief and assurance that God Almighty would descend from heaven and rescue him. His family history was bad, and he believed that he had been born as much of a lunatic as he was to-day. He could not unreservedly agree with Dr. Hammond. This was a question not of retribution upon a disgusting and revolting wretch; but whether the example would frighten other lunatics. This, he believed, would not be the case.

Dr. GEORGE M. BEARD said that he believed in simple terms, and hence did not like the expression, "reasoning mania." He preferred Esquirol's phraseology, and would say *affected monomania*, or simply *monomania*. As to the execution of Guiteau, he thought it would be, from a scientific point of view, the greatest disgrace that ever befell this country. Even during the time of the trial there had been insane murderers who were not so much as tried, and others who were acquitted, with less evidence in their favor. As a principle, the hanging of Guiteau would be a return to the barbarism of the Middle Ages. The whole course of the prosecution had been analogous to the Salem witchcraft trials. There, also, the old dogma about knowing right from wrong had prevailed. Insane murderers usually did know right from wrong, and it was because a murder was a terrible thing that the insane man committed it. If we carried out the doctrine of condemning every man who knows right from wrong there was no safety under the law: trial must lead to conviction, and trial under such a dogma was conviction.

Dr. EDWARD MANN said that he thought most of those present would concede that the greater part of our knowledge on the subject of insanity was derived from Esquirol, and he could not possibly see how intelligent physicians could follow this great authority and yet pronounce Guiteau sane.

Dr. LANDON C. GRAY, of Brooklyn, also acquiesced in the insanity of Guiteau, and recommended that every such criminal should be sent for life to an asylum where the superintendent should be powerless to release him, and that there should be no pardoning power vested in the governor in such cases.

After some remarks by Dr. M. H. HENRY, Dr. SAYRE stated that he regretted very much that the suggestion made by him-self at the time of the murder had not been carried out, namely, that the investigation into the sanity of Guiteau should be made before the trial. It would be much better that the assassin should be shown to be insane than that the idea should prevail that any other than a maniac would dare to shoot the head of this free and enlightened republic.

The Hon. CLARK BELL, president of the Society, then made an address, during the course of which he quoted the answer made by fifteen judges to the House of Lords in consequence of the trial of McNaughten (only Justice Maule dissenting), as to certain of the questions, as follows: "That notwithstanding the party committed a wrong act while laboring under the idea that he was redressing a supposed grievance or injury, or under the impression of obtaining some public or private benefit, he was liable to punishment." The jury ought in all cases, he said, to be told that every

man should be considered of sane mind until the contrary was clearly proved in evidence. Differing from many of his profession, the author of the paper had taken the view generally held by the bar and by the judiciary, and had contended that an insane criminal should be held to the same responsibility as the sane if he was able to understand the nature of his act and its consequences, and to discriminate between right and wrong. While it was undesirable to distrust the verdict, which was generally acquiesced in, the mental state and true condition of the assassin formed an important question in forensic medicine to-day.

Before Dr. Hammond brought the discussion to a close, Mr. Scoville, Guiteau's counsel, who had come into the meeting late, made a few remarks, in which he denied the correctness of the assertion that so long as the insane person knew the criminal nature of his act he was liable to the penalty of the crime. He did not accept the McNaughten case as representing the practice of the courts either in England or the United States. If such were the case, then logic would compel them to remove three fourths of all the insane from the asylums, and place them on trial before the courts. "My investigation of this subject," he said, "has led me to this conclusion: that the court, with some degree of humanity, will find some mode of modifying the law so that while they hold to its spirit they do not hold to its letter. In a case like the Guiteau trial they depart from the rules just to the extent that public opinion demands it; if the public opinion demands it, then the rules are wholly departed from."

#### PROCEEDINGS OF THE GYNÆCOLOGICAL SOCIETY OF BOSTON.

HENRY M. FIELD, M. D., SECRETARY.

STATED meeting, first Thursday of DECEMBER, WM. G. WHEELER, M. D., president, in the chair.

Dr. STOKER made brief but earnest remarks inspired by the recent deaths of Prof. J. P. White, of Buffalo, and of Dr. Theophilus Mack, of St. Catharine's,—both honorary members of the Society,—and then read resolutions of regret and respect which, upon vote, the secretary was instructed to forward to the respective families of the deceased.

#### NEW ATTACHMENT FOR UTERINE FORCEPS.

Dr. GRAINGER, of East Boston, was introduced, and requested to show an instrument of his invention, designed for attachment to the uterine forceps.

The forceps which the doctor had selected was that known as the Elliott, upon the left blade of which Dr. Grainger had fitted a flange, into which could be introduced a slightly curved steel rod, with handle at proximate extremity. Its design is, in case of application of the forceps to the head still above the superior strait, to enable the operator to exert a force which shall be directed downwards and backwards, by which the presenting part shall be returned to its proper position in line with the axis of the parturient canal. The apparatus, it was maintained, was a simple one, and simple in its use. With a reasonable degree of ease it could be employed with perfect safety, and, in the exhibitor's experience, with great satisfaction.

Dr. WHEELER emphasized the difficulty with which all gentlemen are familiar in the case of forceps appli-

cation to the head still above the upper strait. More than twenty years ago he had resorted to a device of his own, calculated to accomplish the same purpose as that which Dr. Grainger had done more effectively by his instrument. His patient was placed upon her back, and drawn well to the edge of the bed, a linen or cotton-cloth band was then placed over the forceps, after they had been locked, at a point as far away from the hands of the operator as possible. This, passing to the floor, was caught by the foot, and thus a downward and slightly backward force was applied in addition to that imparted by the hands in the usual manipulation of the forceps.

DR. MARCY compared the Grainger adjustment with the method of Tarnier. The former appears to be more simple, because it can be kept out of the way, and it is only obtruded upon occasion when it is wanted.

DR. W. S. BROWN had been accustomed to meet the difficulty under discussion by calling to his assistance the hand of the husband, having first instructed him as to the purpose of the aid he was to render.

DR. MARCY called for the experience of any gentleman present in the use of Tarnier's instrument, but it appeared no one was practically familiar with it. The doctor moved the thanks of the Society to Dr. Grainger, which were unanimously passed.

#### LIGATURE NEEDLE.

DR. MARCY exhibited his needle for the purpose of ligating the large pedicle of a tumor, — for example, fibroid or ovarian. It consists of a modification of the Skeeue needle, is fixed in a firm handle, is about nine inches long, and has the eye one inch from the point. The eye is much larger than usual, and, being cut upon the one side completely through, affords sufficient elasticity to aid in the unthreading. The point is nearly round, and thus avoids cutting through the tissues. Commencing at one side, the needle, armed with the ligature (carbolized tendon preferred), is thrust through unthreaded, the opposite end being adjusted and withdrawn. Thus, from opposite sides, each end is drawn through the same opening, and the process is repeated, dividing the mass into as many parts as may be desired, — the cobbler's or shoemaker's stitch. Such ligature is claimed to be not only safe as preventing hemorrhage, but it has the further advantage that when it is properly applied it does not produce necrosis of the tissues, and may thus be safely returned into the abdominal cavity. The animal ligature is either absorbed or transformed into connective tissue, and little irritation ensues. This method of ligature has a further advantage, which, with animal ligatures, is important, of being secured with only one knot, even if many stitches are required.

The doctor also exhibited a specimen of ligature, of exceptional fineness and firmness, contributed by Dr. Simons, of Charleston, S. C., and obtained from the tail of the large fox-squirrel of the South. Dr. Simons had used ligatures from this source with much satisfaction.

DR. W. S. BROWN observed that in the needle used by Spencer Wells the point was blunted. He thought Dr. Marcy's needle had so sharp a point as to lead to the danger of the transfixing of a blood-vessel.

#### EXTRA-UTERINE PREGNANCY.

DR. MARCY showed a pathological specimen of a uterus and appendages, with the following history: —

The woman from whom the specimen was taken had died suddenly, and the case was obscure; moreover, she had presented the singular feature of a temperature as low as 96° F. Autopsy showed the uterus enlarged by multiple fibroids, and the left ovary containing a cyst of about the size of an English walnut, which, upon being opened, was found to contain a collection of the macerated bones of a fetus. The case was interesting as showing a successful effort of nature to repair what would otherwise have been a fatal blunder. On the opposite side were evidences of salpingitis and a degenerated ovary, and yet this ovary contained a corpus luteum of recent menstruation, and the patient had menstruated a short time before death.

DR. STORER gave the points of

#### A COMPLICATED CASE OF PREGNANCY

to the following effect: —

The patient, the wife of a physician, had been married several years, and had miscarried some time since. Had had previously an attack of dysentery, from which she had nearly died. She was now eight months advanced in pregnancy; upon both occasions had fixed conception by a peculiar attack of fainting experienced. Had menstrual discharge two months after supposed beginning of pregnancy. At the third month intolerable pain set in at the lower part of the abdomen, and this has since continued, with somewhat of a periodic character. Had been treated as for intermittent fever without avail. The question is whether the pain does not depend on some abdominal lesion, set up at the time of dysentery, such as a peritonitis with bands of organized lymph, such as we sometimes see in a post mortem. She very early began the use of hypodermic morphia; afterwards, still to obtain relief, and in order to avoid recourse to morphia, she tried chloroform, and soon developed a similar craving for this narcotic. Then bromide of potassium with chloral was tried, and coca was brought in to satisfy the craving appetite. The case persists with its peculiar features, as detailed, but the patient is now near full term. She has at times attacks of maniacal excitement if the morphia be withheld.

DR. FIELD asked if suppositories of morphia and belladonna had been tried, as producing less emphatic impression upon the nervous system than hypodermic morphia, allowing the combination with belladonna, and meeting regional considerations. Reply. They had, with good degree of success.

DR. W. S. BROWN asked if the patient had been examined under anesthetics. Reply. She had, without affording any more positive information.

DR. WHEELER recalled a case in which he operated some years ago for strangulated hernia; abscess followed and extreme pain for months, leading to the inference that some small, sensitive nerve filaments had been drawn into and fixed in the cicatrix. Should suspect, in Dr. Storer's case, the dysentery was responsible for the mischief.

DR. STORER rejoined the mania had been at times markedly suicidal. Physicians ought, more generally and always, to give attention to slight abdominal symptoms in the female, on account of possible subsequent developments or complications. They require greater care for this reason, and closer watching than male patients. Here is suggested one of the many occasions in which gynecology treads closely upon the steps of general practice.

DR. MARCY remarked the case appeared to him more like one of nervous disturbance; he suspected the pain was to be referred to a different set of centres than would be involved if we supposed it dependent directly and altogether on some abdominal lesion. Furthermore, in case of peritoneal adhesions the progress of pregnancy helps the patient.

DR. FIELD believed there was something psychologically wrong, so to speak, about the patient; she had not used opium long enough to develop an opium appetite before the morbid craving showed itself. Furthermore, it was not opium alone that was demanded, as with the opiophagi; there seemed to be a constant appeal for something which should produce both stimulation and repose, — now opium, again chloroform, coca, etc.

DR. WHEELER said that, barring local pain, we should call the case one of puerperal mania.

The Society hereupon went into executive session, during which C. W. Stevens, M. D., of Charlestown, and Samuel M. Nelson, M. D., of Boston, were elected to active membership.

### Recent Literature.

*A Manual of Midwifery.* By ALFRED MEADOWS, M. D., Lond., F. R. C. P., assisted by ALBERT J. VENN, M. D., M. R. C. P. New York: G. P. Putnam's Sons. 1882. 498 pages.

In 1876 we had occasion to express our regret that Dr. Meadows should allow a new edition of his work to appear without attempting to improve on the previous publication. We are now called to review a fourth edition, which the publishers announce as revised and enlarged. We have carefully examined the work, and are somewhat curious to know what assistance could have been rendered by Dr. Venn. The form of the book is altered from one which was easy to hold to the thick and bulky form of a student's manual. There are no changes worth noticing in the work. Three of four pages on abdominal supporters have been omitted, with the plates which illustrated them, and a few paragraphs have been added in which brief allusion is made to the use of the hydrate of chloral. Porro's operation, puerperal thrombosis, and hæmorrhage. We doubt if the few paragraphs added equal in amount the pages omitted, so that we are at a loss to see in what the "enlargement" of the work consists. The publishers have not even taken the trouble to change the numbering of the illustrations, so that one looks in vain for engravings numbered from 122 to 129 inclusive. Nearly six years ago we pronounced the work as unworthy of the writer, and the six years that have since passed seem to us to have only added to the imperfections of the book.

*Illustrations of Dissections in a Series of Original Colored Plates Representing the Dissection of the Human Body.* By GEORGE VINER ELLIS, Professor of Anatomy in University College, London, and G. H. FORD, Esq. Volume I. Second Edition. New York: William Wood & Co. 1882.

This is the first volume of a work that we shall be glad to see completed, for although neither the dissec-

tions nor the descriptions display much originality, they are both satisfactory, and it is well that a series of colored plates of good dissections with simple descriptions should be within the reach of the student. These few words will suffice to express our general opinion of the book. Were it more pretentious it might call for severer criticism; but it makes no claim to present a system of anatomy, nor should the occasional practical deductions be discussed as if they appeared in a surgical text-book. The plates are reduced in size so that they may be brought into an octavo volume. Many are very handsome and well executed, a few are feeble and rather indistinct.

*Illustrations of Dissections.* By GEORGE VINER ELLIS. Volume II. New York: William Wood & Co.

The second volume calls for little additional comment, for the general remarks which we made on the first are equally applicable to it. There is perhaps a larger proportion of surgery in this volume, which includes the important regions of the pelvis and of the groin. It is perhaps to be regretted that these dissections stop short of the deepest parts, and that little if anything is said of the bones and joints.

T. D.

— Dr. Mikulicz, of Vienna, describes an instrument by means of which he and Dr. Leiter have been enabled to inspect the interior of the stomach of living persons. The instrument consists of a long tube, containing an insulated double electric wire, two water-channels, a fine air-channel, and a means of electric lighting for the optical apparatus. The tube is stiff, but has an angle at the junction of its lower and middle thirds, where a reflecting prism is introduced. It is passed while the patient is in a condition of morphia-narcosis, lying on his side. The stomach is washed out through the water-channels and air is pumped in through the air-channel to afford a fit medium for the inspection. Dr. Mikulicz has hitherto confined his examinations almost entirely to healthy individuals, and therefore is not yet in a position to offer much information on the value of the gastroscope for diagnostic purposes. — *The Practitioner, from the Centraltblatt für Chirurgie, No. 43, 1881.*

— In filling the position of surgeon to the Great Western Railway, England, a position worth six hundred pounds per annum, the authorities were obliged to make a selection from over six hundred candidates.

— The Pennsylvania College of Dental Surgery held its twenty-sixth annual commencement at the Academy of Music, February 25th, graduating fifty students, the address being delivered by Prof. W. F. Leitch, and the valedictory by M. H. Feltzer, D. D. S., from the graduating class.

— The Philadelphia Dental College held its nineteenth annual commencement March 1st, graduating fifty-two students. An address was delivered by J. Foster Flagg, D. D. S., Professor of Dental Pathology and Therapeutics, and the valedictory by Leon F. Head, D. D. S., a member of the class.

# Medical and Surgical Journal.

THURSDAY, MARCH 16, 1882.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

## ICE-WATER.

OUR esteemed contemporary, the *British Medical Journal*, of a late date, indulges in some remarks on the above subject, which we think will scarcely profit its English readers, and are not required by its American:—

The prevalent dyspepsia from which Americans suffer so much, and which is so apt to undermine the strength of the men and the bloom of the women of America, is in a large measure due, we believe, to the universal habit of drinking large quantities of ice-water. This essentially transatlantic habit has long been a speciality of which our American friends and travelers seem to be proud, complaining that they find the purest water in England undrinkable from the difficulty of getting water to drink with lumps of ice floating about in it. Nothing can be more destructive to the utility of the process of digestion than this habit. There is, however, another danger inherent in this mode of introducing ice, to which attention has more than once been called by sanitary authorities in this country, and which, we note with interest, is now also attracting notice in America. It hardly needed the scientific experiments of Professor Pumpelly—an authority whose name is singularly appropriate to the investigation—to prove again that the freezing of organic impurities and diseased germs does not deprive them of vitality, but only suspends their activity, and that frozen water is apt to entangle a large proportion of the floating impurities which may be suspended in it; and that it is probably quite as easy to contract typhoid fever from impure ice as from impure water. The habit of drinking ice-water is altogether a bad one, and may readily become a source of serious or fatal illness if the ice be impure.

Habits of life are very apt to be determined by climate and general surroundings, and the instincts of natives are guides which strangers would do well to respect more often than they do, as many an English liver protests after being tyrannized over by its owner for some years in India.

Barring the question of alcohol, we permit ourselves to suppose that in England a native should be a fair judge of the ingesta demanded by his system, but he will not remember that the English climate is one thing, that of India another, and that of the United States—if the two last countries can be said to have any one climate—still another.

A high temperature with a dry atmosphere, favoring rapid evaporation, create a natural demand for more fluid to replace loss and to sweep away waste products, and cold water is found to be more palatable and more refreshing than warm. We have large quantities of ice, and we use it freely, and our personal observation leads us to think that as ice in England improves in quality, and becomes more abundant by import or manufacture, it is more largely and more generally used.

Americans who have traveled there in former years will recall the utter impossibility of finding ice even

in the hottest days of summer, and the not unusual response to a call for water of, "Yes, sir; hot water, sir?"

Bad ice is much less often encountered than bad drinking water, in fact with us it is rare, but it is neither the British scientist nor Professor Pumpelly who first called our attention to the dangers of using it. In the Seventh Annual Report of the Massachusetts State Board of Health, that published in January, 1876, is a report by Dr. A. H. Nichols, on an outbreak of intestinal disorder, attributable to the contamination of drinking water by impure ice, which we commend to the attention of our esteemed contemporary, only having space for the closing paragraph, namely:—"The notion that ice purifies itself by the process of freezing is not based upon trustworthy scientific observation. On the contrary, it is utterly wrong in principle to take ice for consumption from any pond the water of which is so fouled as to be unfit for drinking purposes." Since the publication of the above paper this subject of impure ice as a source of intestinal and other disorders has been discussed and borne in mind both by the profession and the public in this country, but, though not denying its possibility, we have yet to learn of genuine typhoid fever conveyed in this manner.

Moreover, without wishing to magnify a small matter, we must take exception to such dogmatic statements as that "nothing can be more destructive to the utility of the process of digestion than this habit," or that "the habit of drinking ice-water is altogether a bad one," and protest, "not proven." That the Americans are a dyspeptic people is unfortunately too true, but we think our neighbor has exalted a coincidence into a cause.

In the *Archives of Medicine* (New York) for August, 1880, there appeared an article by S. G. Webber on Water as a Prophylactic and a Remedy to which we applied at the time, in the course of some editorial comments, the words "timely and sensible," and in which the author declares that his experience leads him to believe that as a rule the contrary extreme to that attributed to us by the *British Medical Journal* is in the ascendant, and that Americans do not drink enough water.

We can undoubtedly still learn much from England and Englishmen for our profit on many subjects, but we doubt if ice and ice-water should be placed prominently among them.

## VITAL STATISTICS IN ENGLAND AND GERMANY. COMPARATIVE MORTALITY TABLES.

THE January number of the *Vierteljahrsschrift für Gerichtliche Medizin und öffentliches Sanitätswesen* (Berlin) contains a paper by Dr. Ebertz, in which the mortality and causes of death in England and Germany for the year 1880 are compared. The tables given are compiled from the weekly returns of the registrar-general and the monthly reports of the medical officers of health in England on the one hand, and from the weekly returns of the German Health

TABLE I. STATISTICS OF MORTALITY IN ENGLAND FOR THE TWENTY LARGE TOWNS, LONDON INCLUDED, WITH A POPULATION OF ABOUT SEVEN AND A HALF MILLIONS, FOR THE YEAR 1880.

|  | JAN.<br>4-31. | FEB.<br>1-28. | MARCH.<br>Feb. 26 to<br>April 3,<br>5 weeks. | APRIL<br>4 to<br>May 1. | May<br>2-29. | JUNE<br>May 30<br>to<br>July 3,<br>5 weeks. | JULY<br>4-31. | AUG.<br>1-28. | SEPT.<br>Aug. 29<br>to<br>Oct. 2,<br>5 weeks. | OCT.<br>3-31. | NOV.<br>Oct. 31<br>to Nov.<br>27. | DEC.<br>1, 1881,<br>5 weeks. |

Bureau and the medical statement for the city of Berlin in Germany on the other hand.

Preventive medicine being already so important a part of the theory and practice of medicine to-day, and tending to become constantly more so, we make no apology for introducing to the notice of our readers an abstract of Dr. Ebertz's tables and conclusions, showing as they do how much may be done to lower the death-rate and diminish the frequency of certain classes of diseases, even under the unfavorable conditions engendered by large centres of population, through the efficient execution of sanitary measures. Moreover, the readers of the JOURNAL are in a position to verify or to continue most of the comparative tables given in Dr. Ebertz's article by the aid of the mortality tables published every week at the end of these pages.

Dr. Ebertz draws the following conclusions from his comparison of the mortality returns of the twenty large English towns with an estimated population in 1880 of seven and one half millions, and of the one hundred and forty-nine German towns with an estimated population of seven and three fourths millions, of London and Berlin, of individual small towns, and of rural districts in the two countries having similar populations:

(1.) A comparison of the relative mortality of England and Germany for the year 1880 is not favorable to the German cities. (2.) The mortality in general in Germany, and especially the mortality of children, was much higher in Germany than in England. (3.) The mortality of Berlin compared with that of London make an especially unfavorable exhibit. (4.) The mortality of children in Berlin in the summer months compared with that of children in London in the same months is enormous. (5.) The death-rate among children was smaller in London than in the other large English towns, and in these again than in the country districts, which is a striking example of the favorable results reached by London, particularly, and the other large towns in the domain of sanitary prophylaxis. (6.) No less forcible testimony to this is the fact, shown by the English tables, that not only in the country districts, but also in the large towns, and eminently in London, the mortality from infectious diseases was less than the mortality from diseases of the respiratory organs, even excluding phthisis.

These conclusions, Dr. Ebertz reflects, are of the

utmost interest to Germany, proving as they do, by figures, that the English sanitary organizations have contended more effectually against the dangers to health incident to life in large cities than the German have succeeded in doing, and he believes that a thorough study of English work in sanitation will bring his countrymen much nearer the greatly-to-be-desired end of reducing their still high death-rates at least to the scale of the English.

We have condensed some of the most interesting of the tables which Dr. Ebertz has worked out from the English and German reports; the results given by these reports are really of some positive value, as the death returns are under government control, the estimated populations are a near approximation to the actual populations, and similar quantities are, in nearly every case, used for purposes of comparison.

At the same time, in comparing the vital statistics of cities like London and Berlin with each other, and with those of small towns and country districts, it must not be forgotten that there are certain conditions which modify without reversing the general results arrived at. Berlin, for example, has certainly a much hotter and less healthy summer climate than London, the proportion of children to the total population is, we believe, larger; and, again, in all large cities, and especially in a place like London, the population is constantly recruited by the most active and vigorous young people from the surrounding country.

From Table 1. the following average rates per thousand for the English cities for the year 1880 result: the birth-rate was 36.1, the general death-rate, 22.8; the death-rate from acute diseases of the respiratory organs, 4.5, from the seven infectious diseases, 4.

The statistics of mortality in Germany, taken by Dr. Ebertz from the Weekly Statements of the Government Health Bureau for the Year 1880, and exhibited in Tables VI. and VII., apply to one hundred and forty-nine German towns with a population of fifteen thousand and over, and a total population of somewhat more than seven and one half millions; Berlin is included with a population of 1,080,000. In some points, for example the mortality from infectious diseases and acute diseases of the respiratory organs, a difference in classification renders a useful comparison with the English returns impossible, and therefore none has been attempted for these diseases.

Tables VIII., IX., and X. give comparisons in figures between English and German mortalities as deduced from the preceding. The twenty large English towns, population 7,500,000, the English rural districts, population 7,500,000, the one hundred and forty-nine German towns, population 7,775,000, London, population 3,600,000, and Berlin, population 1,080,000, are taken for comparison.

### JOSEPH PANCOAST.

JOSEPH PANCOAST, M. D., Emeritus Professor of Anatomy in the Jefferson Medical College, died at his residence in Philadelphia, Tuesday, March 8, 1882, in the seventy-seventh year of his age. For the last five years, on account of failing health, he had led a very quiet life, retiring entirely from professional and professorial duties. About two years ago he sustained a severe shock from a fall down stairs; injuries to the nervous system were then received which rendered him since that time an invalid, although not constantly confined to his room. A few days ago, from a sudden change in the weather, he caught a severe cold, and congestion of the lungs developed which was rapidly fatal.

Professor Pancoast, a native of Burlington, New Jersey, was born in 1805. He was graduated from the University of Pennsylvania in the Medical Department in 1828; soon afterward he entered the Philadelphia Hospital as resident physician. In 1831 he commenced teaching anatomy, and three years later was elected one of the physicians to the Philadelphia Hospital, and from 1838 to 1845 he served as a visiting surgeon in the same institution. He was also appointed surgeon to the Pennsylvania Hospital in 1854, a position he held for ten years, when his increasing duties compelled him to resign. Elected by the Board of Trustees of Jefferson College to fill the vacancy caused by the retirement of Dr. George McClellan in 1838, he filled the Chair of Surgery until 1861, when he took anatomy, dividing the surgical clinic with the Professor of Surgery; in 1874 he was elected Emeritus Professor of Anatomy. He took for thirty-six years an active part in the Faculty during the most important stage of the history of the school, adding greatly to its strength by the brilliancy of his operations, the originality of his methods, and the marvelous success he achieved in clinical surgery; he won a world-wide reputation and, probably more than any other individual, contributed to the remarkable success of the Jefferson Medical College. Dr. Pancoast had much artistic taste; he handled the brush as well as the surgeon's knife, and illustrated his lectures with large paintings by his own hand; it is difficult to realize, at the present time, the amount of enthusiasm that his clinical lectures excited; he delighted in obscure and apparently hopeless cases, and as he observed the rule of exhibiting the patients from time to time in order to demonstrate the progress of treatment, the greatest interest was excited in his class, and his clinic day often appeared like an ovation. He was greatly liked by the students, who,

recognizing his genius, took every opportunity of manifesting their appreciation of his ingenuity and originality.

Among the operations and surgical expedients devised by Professor Pancoast the one with which his name has been most intimately connected and best known is the improved abdominal tourniquet for compression of the aorta during amputations of the thigh or hip-joint. In the treatment of obstinate facial neuralgia he several times performed resection of the inferior branch of the fifth nerve at the point of emergence from the foramen ovale; and he was one of the first in this country to operate in cases of empyema by paracentesis.<sup>1</sup> In 1868 he devised his operation for extrophy of the bladder, which he performed with success; and good results have since been obtained from it by other operators both in Europe and America. An improvement in the rhinoplastic operation, which he termed the plough and groove suture; a modification in the treatment of cataract (soft and mixed), the introduction of a soft ivory tube in stenosis of the nasal duct; a plan in plastic surgery for restoring an eyebrow; and numberless other expedients showing his greatness as a surgeon, he brought to the notice of the profession.

He had considerable literary ability as well as great industry. In 1831 he translated Lobstein's Treatise on the Structure, Functions, and Diseases of the Human Sympathetic Nerve, to which he added notes; in 1844 he published his Treatise on Operative Surgery, which passed through three editions. He also remodeled and reissued Wistar's Anatomy in 1844, and edited Manec on the Great Sympathetic Nerve, and the Cerebro-Spinal System of the same author, and subsequently an American edition of Quain's Anatomical Plates, besides being a frequent contributor to the *American Journal of the Medical Sciences*, and the now defunct *American Medical Intelligencer*, and the *Medical Examiner*. His introductory addresses and other public lectures were numerous; after a tour of Europe in company with Professor Gross, where they received the highest honors, he embodied some of his reminiscences in an address delivered in 1856, entitled *Professional Glimpses Abroad*, which attracted much attention.

Professor Pancoast had many social ties and was fond of society; he was a prominent figure in the Wistar parties that are full of so many pleasant recollections to the older generation of physicians. He was a Fellow of the Philadelphia College of Physicians, and a member of the American Philosophical Society, of his County and State Medical Societies, and other scientific institutions, American and foreign. To properly estimate the character and attainments of such a man as Pancoast, and his influence upon medical thought and medical practice, is no easy task; he occupied a prominent place in surgical practice during the period of greatest activity and greatest growth of medical science that the world has ever known, and he filled it worthily.

<sup>1</sup> American Journal of Medical Sciences, 1829.

## MEDICAL NOTES.

— A sailor, recently from Philadelphia, was admitted to the Hospital, Monday, March 13th, with small-pox; but three other patients remain in Hospital, all considered well but not yet discharged.

— Meharry Medical College, the negro medical school of Nashville, Tennessee, graduated a class of eight at its recent commencement.

— A new street in the neighborhood of the General Hospital in Vienna is to bear the name of "Skoda Street" (*Skodagasse*), in honor of the celebrated physician and clinical professor.

## PHILADELPHIA.

— Professor Joseph Pancoast died at his house in Philadelphia, on Tuesday, the 7th inst. [A notice of his death appears in another column.]

— At the last meeting of the College of Physicians the death of Professor Robert Bridges was announced, and resolutions of respect entered upon the minutes of the meeting. Dr. Bridges, after lecturing in the Philadelphia College of Pharmacy for thirty-seven years, was obliged, from failing health, to resign the active duties in the Faculty in 1879, when he was elected Emeritus Professor of Chemistry, with a salary of one thousand dollars during his life, in recognition of his long, faithful, and valuable service. He took the position of librarian to the College of Physicians in 1868, which he held until December, 1880, when he had a severe attack of cystitis, which greatly undermined his strength; he never was able to resume his duties, and finally resigned the position in March, 1881. For a year his health has been precarious, and for the last few months it became evident that he was rapidly nearing the close of a long and useful life; he was in the seventy-sixth year of his age at the time of death, which occurred on the 20th ult. Dr. Bridges for many years was Assistant Editor of the *American Journal of Pharmacy*, and contributed, though rarely, to other journals. He was well known as the editor of the American reprint of Fownes and Graham's chemistries, and as the chemical editor of the United States Dispensary after the death of Dr. Baché. Besides being a Fellow of the College of Physicians he was a member of the American Philosophical Society, and also of the Philadelphia Academy of Natural Sciences, of which he was for many years the first vice-president, and frequently presided at its meetings. Though of kind and agreeable manners, he cared little for the claims of general society, and never married. He was universally respected and esteemed for his many excellent qualities of mind and heart.

— Small-pox is declining in this city; the total number of deaths from this cause for the first two months of this year was only 125, being a decrease of 271 from the corresponding period of last year; during the same time 605 cases were reported, a falling off of 991 from the record of last year.

— Dr. Lewis S. Pilcher, of Brooklyn, read a paper before the Philadelphia County Medical Society On the Ligation of Large Venous Trunks, on Wednesday

evening, March 8th. After the regular meeting a very pleasant social reception was held by the Society in honor of the lecturer of the evening.

— The College of Physicians has decided to open a registry for nurses upon the plan of that in Boston; it is expected that every required arrangement will be completed by the first week in April. At the March meeting of the college a paper was read by Dr. W. F. Atlee, in which he reported a rare case of fungosities of the bladder, where removal by scraping relieved all the urgent symptoms, and permitted re-establishment of health; there had been no evidence of a return of the disease although the operation was performed nearly two years ago. Through the energy of one member of the publication committee papers have been pledged sufficient to provide interesting material for discussion at the regular meetings for the next three years.

## Miscellany.

## ASYLUM STATISTICS. REPLY FROM DR. H. B. WILBUR.

MR. EDITOR. — In the number of your journal for February 23d I find an article headed *The Value of Statistics as to Insane Asylum Management*. As it contained some rather sweeping assertions about a table of statistics that was a part of a late paper of mine in the *Archives of Medicine*, I desire the use of your columns to make a brief reply. The table in question is spoken of as "entirely untrustworthy;" that "as a basis of comparison it is absolutely worthless."

As most of your readers have doubtless not seen the article criticized, and so cannot judge of the fairness of the criticism, my desire to set myself right before them will hardly be regarded as unreasonable.

The object of my paper may be summarily stated. To meet a statement often made in the United States, that in the British asylums for the insane the necessity for restraint by mechanical appliances is obviated by the free use of stupefying drugs, I prepared some comparative tables showing the relative use of mechanical restraint and the administration of soporifics and sedatives in the asylums of the two countries.

The British table referred intentionally to fifteen institutions where almost no mechanical restraint is used and very little seclusion, and where the reports of their superintendents show that very little recourse is had to the so-called chemical restraint. The American table, however, made up from the reports of the superintendents of twenty-six asylums, proves that a good deal of mechanical restraint is used in these, and also a very free use of soporific and sedative medication. I knew that this last table was, in a measure, imperfect, and I put a note to that effect at the bottom of it. If all of the American superintendents had been as frank and explicit in making their returns as some of them were the table would have been more complete and instructive, but the comparison, then, would have been worse for the American asylums. The same spirit that led some of the number to whom circulars were sent to refuse or withhold their statistics, prompted others to send only such as would be of little or no value. The imperfection of the table, however, was in part remedied by three pages of explanatory remarks

by the officers of fourteen of these asylums. It was also mentioned that in interpreting the term "occasions" of restraint or seclusion the reporter, as a rule, had called a week or month of continuous restraint or seclusion as seven or thirty occasions, as the case might be.

Statistics may not be strictly accurate and yet entirely adequate, as was the case in this instance. Thus, the table criticized was prepared, not for the purpose of comparing American asylums with each other in the matters under discussion, but to compare the general practice in the asylums of the United States with those of Great Britain and Canada. Now no candid reader, after an examination of the tables I furnished and the other statistics compiled from the English Lunacy Report for 1889, can fail to see, first, that the use of chemical restraint is not greater in Great Britain because of the disuse of mechanical restraint. Secondly, that there is a wide difference in the amount of mechanical restraint used in the insane asylums of the two countries. And, finally, the statistics that I presented prove conclusively that suicides are far more common in our institutions than in the British asylums.

But the statistics were the least valuable portion of my paper. Its value was more in the opinions given by leading specialists upon the subjects of restraint and the use of re-latives, in the remarks that accompanied the statistics. On the British side there was the evidence that the habitual use of drugs to allay maniacal excitement was regarded as somewhat hazardous, and that non-restraint is no bigoted dogma, but a principle that has been the outgrowth of the best medical experience in the management of the insane. On the American side it is equally obvious that there is a growing disposition to break away from the traditions of the past in order to reduce the use of mechanical restraint to a minimum. The "striking" evidence advanced by my critic is that "correct conclusions on the subject of restraint and" "conclusion made up from the records of asylums, are simply impossible," applies only to the statistics of the asylums of one State and the discrepancy there will admit of other explanations, which I need not offer.

SEBASTIAN, N. Y. M. 1982.

Dr. Williams's letter is nothing to the discussion of the matter of our editorial of February 26, and, therefore, does not in any way the views which we stand expressed. Only one who has had experience in the treatment of the disease or in the management of the case, as you call it, are how differently facts appear to him, and in reality, especially when collated with several different persons.—L.H.C.

WAS IT VARGOLICH? WAS IT ROTHEN:

Mr. KIDDER—I read with interest the case reported in the JOURNAL of the 24 inst. by Dr. OLSON, of EXETER, N. H., on a case of Anomalous Case. With a few words, he has given a full and complete history of the case. The water of the pond where the water was taken from, he has not examined, and has not made any other examination, which I anticipated.

cases, but a day or two cleared them up. Some time afterward I called the attention of the members of our District Medical Society to the fact of the occasional occurrence of severe backache in the disease.

JOHN H. GILMAN, M. D.

LOWELL, March 6, 1882.

THE PEABODY DONATION FUND.

The annual report, for the year 1881, of the Trustees of the Peabody Donation Fund for providing lodging houses for the laboring classes in London has been lately made public, and presents some interesting items which we copy from the *Medical Times and Gazette*, February 26th. The report shows that the net gain of the year, from rents and interest, amounted to £23,751. Up to the end of the year the Trustees had provided for the artisan and laboring classes in London 6100 rooms, exclusive of bath-rooms, laundries, and washhouses. The rooms comprised 2787 separate dwellings, occupied by 11,459 persons. During the year 432 new dwellings had been opened, and for these rooms there were upwards of 3000 applicants. The death-rate in the Peabody Buildings for the twelvemonth "was 17.22 per 1000, about 3.98 in 1000 below the average of all London for the same period. The actual number of deaths is taken from returns furnished by the district registrars, and the calculation has been checked and confirmed at the General Register Office." The average weekly earnings of the head of each family in residence at the close of the year was, we are told, £1 2s. 7½d.; and the average rent of each dwelling was 4s. 5½d. per week, and each room 2s. The dwellings consist of from one to three rooms in most of the groups of buildings; but in two groups dwellings containing four rooms are provided. The average weekly earnings of each head of a family does not go very far, however, in showing that some of the dwellings are not occupied by families earning large wages; so the Trustees give also a table showing the employment of the tenants; and they further take the opportunity of answering objections that have been taken to their administration of the Trust. It has been objected, the Trustees remark, that "in following the system upon which they have acted for nearly twenty years they have departed from the expressed intentions of the founder, and that the benefits of the Fund are enjoyed by a class for which they were not originally intended;" and their reply is that Mr. Peabody fully knew and approved of all the proceedings of the Trustees, and was well informed as to the occupations and wage-earnings of the persons inhabiting those buildings that were finished and occupied before his death. The sums given and bequeathed by him were £150,000 in 1862, £100,000 in 1866, £100,000 in 1868, and £150,000 in 1873. The Spitalfields and Islington buildings were finished and occupied before the date of Mr. Peabody's second will; and in acknowledging to the Trustees the receipt of their report issued in December, 1865, he wrote:—"The capital will form a fund, the operation of which is intended to be progressive in its usefulness, as applied to the relief of the poor of London, as correctly stated in your report." In that report, the occupants of the then existing buildings were set forth as in the report now before us, and as including the same classes as now, namely, chamberwomen, monthly nurses, basket-makers, butchers, carmen, carpenters, firemen, laborers, and very large proportion to the other classes), porters

omnibus-drivers, sempstresses, shoemakers, tailors, smiths, letter-carriers, cab-drivers, coster-mongers, turners, policemen, warehousemen, waiters, and the like. Also, in the trust-deed, dated May 31, 1869, prepared under the personal supervision of Mr. Peabody, the following passages occur:—

"The operation of the Fund is intended to be progressive in its usefulness."

"It will act more powerfully in future generations than in the present. It is intended to endure forever; and it is the ardent hope and trust of the said George Peabody, that within a century the annual receipts from rents for buildings of the improved class, hereby authorized, may present such a return that there may not be a poor laboring man of good character in London who could not obtain comfortable and healthy lodgings for himself and his family at a cost within his means."

This hope and trust may appear Utopian; but, at

any rate, the Trustees have a right to hold that "Mr. Peabody fully understood and personally sanctioned the two leading principles on which his Trust has, since its origin, been administered—first, that the buildings shall be occupied by tenants of the working classes paying a reasonable rent; second, that the income thus obtained shall be applied to the construction from time to time of fresh buildings similar to those already existing, so that the operation of the Fund may admit of indefinite though gradual extension;" and a lasting benefit may thus be conferred on the working poor of London.

The sum given and bequeathed by Mr. Peabody was £500,000 and the added money received for rent and interest amounts to £280,418 4s. 9d., making the total Fund on December 31, 1881, £780,418 4s. 9d. — a magnificent fund of which to have the management for the benefit of the working-classes.

Deaths reported 2567 (no reports from Philadelphia and New Orleans); 1060 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 596, consumption 338, lung diseases 436, diphtheria and croup 160, scarlet fever 134, small-pox 82, measles 45, diarrheal diseases 39, typhoid fever 31, cerebro-spinal meningitis 27, malarial fevers 27, whooping-cough 25, erysipelas 12, puerperal fever 12, typhus fever two. From measles, New York 23, Chicago seven, Brook-

lyn six, Pittsburgh four, Buffalo three, Milwaukee and West-borough one each. From diarrheal diseases, New York 10, Boston and Buffalo four each, Brooklyn, Chicago, Baltimore, and Providence three each, District of Columbia and Milwaukee two each, St. Louis, Cincinnati, New Haven, Lowell, and Brockton one each. From typhoid fever, Chicago six, New York, Cincinnati, Pittsburgh, and Buffalo three each, Boston, Baltimore, District of Columbia, and Lowell two each, Brooklyn, Milwaukee, New Haven, Charleston, and Plymouth one

each. From *cerebro-spinal meningitis*, New York 10, Chicago three, St. Louis, Cincinnati and Milwaukee two each, Baltimore, Worcester, Cambridge, Somerville, Chelsea, Fitchburg, North Adams and Peabody one each. From *malarial fever*, New York 13, District of Columbia five, St. Louis four, Chicago three, Baltimore, and New Haven one each. From *whooping-cough*, New York 12, Providence four, Pittsburgh three, Brooklyn two, Boston, Cincinnati, District of Columbia, and Cambridge one each. From *erysipelas*, New York three, Chicago two, Brooklyn, Boston, Cincinnati, District of Columbia, Buffalo, Providence, and Lynn one each. From *puerperal fever*, Chicago two, New York, Brooklyn, St. Louis, Baltimore, Cincinnati, Buffalo, Milwaukee, Providence, New Bedford, and Somerville one each. From *typhus fever*, New York two.

Ninety-two cases of small-pox were reported in Cincinnati, Pittsburgh 68, St. Louis 12, Baltimore seven, Brooklyn five, Buffalo three, Milwaukee three, and Boston one; diphtheria 28 cases, scarlet fever 16, typhoid fever eight in Boston; scarlet fever 14, and diphtheria 10, in Milwaukee.

In 38 cities and towns of Massachusetts, with a population of 1,015,711 (population of the State 1,783,086), the total death-rate for the week was 20.37 against 22.96, and 19.85 for the previous two weeks.

For the week ending February 11th, in 173 German cities and towns, with an estimated population of 8,456,206, the death-rate was 28.6. Deaths reported 4650: under five 2263; pulmonary consumption 607, acute diseases of the respiratory organs 535, croup and diphtheria 296, diarrhoeal diseases 117, scarlet fever 111, whooping-cough 79, typhoid fever 60, measles

and röteln 38, puerperal fever 36, small-pox (Dresden, Hof, Berlin, Aachen, Essen, Colden, Darmstadt) seven, typhus fever (Thorn, Grandzuc, Braumberg) three. The death-rates ranged from 17.9 in Metz to 42.1 in Dortmund; Königsberg 39.7; Breslau 31.5; Munich 37.5; Dresden 25.7; Berlin 25.3; Leipzig 27.3; Hamburg 50.2; Hanover 24.6; Bremen 23.1; Cologne 31.9; Frankfurt-on-Main 20.4; Strasburg 26.3.

[The arrival of the present English weekly return was delayed, and it is published now out of turn not to break the series. — Ed.]

In the 28 English towns, with an estimated population of 8,455,320, for the week ending February 11th, the death-rate was 29.8. Deaths reported 4832: acute diseases of the respiratory organs (London) 994, whooping-cough 336, measles 117, scarlet fever 93, fever 53, diarrhoea 31, small-pox (London) 17. The death-rates ranged from 14.5 in Birkenhead to 35.3 in London; Leeds 21; Birmingham 21.2; Sheffield 23; Bristol 24.1; Liverpool 27.3; Manchester 32.2. In Edinburgh 18.9; Glasgow 28; Dublin 33.6.

For the week ending February 18th in the Swiss towns, population 479,934, there were 43 deaths from acute diseases of the respiratory organs, pulmonary consumption 40, diphtheria and croup 18, diarrhoeal diseases 15, scarlet fever and whooping-cough five each, typhoid fever three, puerperal fever one. The death-rates were, Geneva 36.1; Zurich 31.7; Basle 34.2; Berne 39.1.

The meteorological record for the week ending March 4th, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps: —

| Date.                        | Barom-eter. |    | Thermom-eter. |          |          | Relative Humidity. |            |             | Direction of Wind. |            |            | Velocity of Wind. |            |            | State of Weather. <sup>1</sup> |            |            | Rainfall.   |                       |                   |

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 4, 1882, TO MARCH 10, 1882.

POWELL, J. S., first lieutenant and assistant surgeon, Fort Stockton, Texas. Granted leave of absence for one month. S. O. 19, Department of Texas, February 24, 1882.

NEWTON, R. C., first lieutenant and assistant surgeon. When relieved by Assistant Surgeon Conneys to proceed to Fort Cummings, New Mexico, and report to the commanding officer for duty. S. O. 40, C. S., Department of the Missouri.

ALEXANDER, R. H., major and surgeon. Now awaiting orders, to report in person to the commanding general, Department of the Missouri, for assignment to duty. S. O. 52, A. G. O., March 6, 1882.

BROWN, H. E., major and surgeon. Now awaiting orders, to report in person to the commanding general, Department of the South, for assignment to duty. S. O. 52, C. S., A. G. O.

DICKSON, J. M., captain and assistant surgeon. Now awaiting orders, to report in person to the commanding general, Department of the East, for assignment to duty. S. O. 52, C. S., A. G. O.

LAUDERDALE, J. V., captain and assistant surgeon. Relieved from duty in the Department of the South, and to report in person to the commanding general, Department of Dakota, for assignment to duty. S. O. 52, C. S., A. G. O.

FINLEY, J. A., captain and assistant surgeon. At expiration of his present leave of absence to be relieved from duty in the

Department of the East, and to report in person to the commanding general, Department of Texas, for assignment to duty. S. O. 52, C. S., A. G. O.

GARDNER, EDWIN F., captain and assistant surgeon. To report in person to the President of the Medical Examining Board, in session in New York city, for examination for promotion, and on its conclusion to report by letter to the Surgeon-General. S. O. 52, C. S., A. G. O.

ROBINSON, S. Q., captain and assistant surgeon. To report in person to the President of the Medical Examining Board, in session in New York city, for examination for promotion, and on its conclusion to report by letter to the Surgeon-General. S. O. 52, C. S., A. G. O.

FRANTZ, JOHN H., major and surgeon, died at Baltimore, Md., March 2, 1882.

BOOKS AND PAMPHLETS RECEIVED. — The Human Ear and its Disorders. A Practical Treatise upon the Examination, Recognition, and Treatment of Affections of the Ear and Associate Parts. Prepared for the Instruction of Students and the Guidance of Physicians. By W. H. Winslow, M. D., Ph. D., Oculist and Aurist to the Pittsburgh Homoeopathic Hospital. One hundred and thirty-eight illustrations. Boericke and Tafel, New York and Philadelphia. 1882.

Fifth Biennial Report of the Trustees, Superintendent, Steward, and Treasurer of the Iowa Hospital for the Insane at Independence (Iowa), for the Fiscal Years of 1880 and 1881. Printed by order of the General Assembly.

FOREIGN BODY IN ŒSOPHAGUS; ŒSOPHAGOTOMY; DEATH IN SIXTY HOURS AFTER OPERATION.<sup>1</sup>

BY D. W. CHEEVER, M. D.

C. A. G., forty-four years old, native of Connecticut and resident in Boston, single man, a seafaring man the most of his life, but for the past year or two a bar-keeper, came to the Boston City Hospital at noon of Tuesday, December 13th, giving the following history. While eating breakfast (halibut steak) the Saturday previous he got a fish-bone in his throat. Saw a physician within twenty minutes, who, after trying in vain to remove it, called a second and they, together, passed a bristle probing three times without removing the bone. From that time on pain and tenderness in the throat gradually increased. He soon became unable to swallow solids, and could swallow liquids only with extreme difficulty, taking no nourishment after the accident but a little milk and brandy. He gradually became unable to swallow even liquids, and, finally, saliva. Hoarseness and cough gradually became prominent symptoms.

When seen by Dr. D. W. Cheever, seventy-six or seventy-seven hours after the accident, he was evidently in great distress. Pulse 108; temperature not taken. Respiration rapid; hoarse; considerable cough; swelling and œdema of both sides of neck, a little above the level of the cricoid cartilage, but more marked on the right side. A feeling on pressure as if a sharp point was sticking into him on both sides of his throat. Inspection of fauces showed no disease or inflammation of any part in view. Passing the forefinger deeply into the throat, Dr. Cheever failed to reach any foreign body, although he could get beyond the tip of the epiglottis. Patient was a short, thick-set, full-necked man with a complete set of teeth, and, owing to the swelling of his neck, opened his mouth with some difficulty, so that it was impossible to reach beyond the larynx with the finger, as can be done on a favorable subject. The symptoms present indicated a foreign body still in the throat, but were not simply those of a foreign body in the alimentary tube; cough, hoarseness, laryngeal spasm, and rapid respiration giving some plausibility to the theory of a foreign body in the air-passages. When, however, the patient attempted to swallow a little water, he seized the back of his neck with both hands, put all the voluntary muscles in most rigid tension, and, finally, with a painful gasp, got the liquid down. This fact seemed entirely inconsistent with the presence of a foreign body in the air-passages. An additional reason for thinking the air-passages free was the fact that three days had elapsed without the occurrence of persistent croup (from œdema of the glottis) or constant bronchial cough, which Dr. Cheever had seen present in all other cases. The diagnosis of a foreign body in the upper part of the alimentary canal having been made, the length of time it had been there, the previous ineffectual attempts to remove it, the œdema and swelling of the neck, the rapid pulse and febrile condition of the patient, was thought to forbid any more active interference through the natural passages. Œsophagotomy

was proposed and the patient assented, it having been explained to him that he must run some hazard if he wished to save his life.

The patient was etherized with some difficulty owing to spasm. The tongue was threaded so as to be readily pulled forward, should occasion require, as was often the case. The patient was placed with his shoulders raised, head back, and face turned obliquely toward the right. Dr. Cheever began by an incision in the left superior carotid triangle, parallel with the sterno-cleido-mastoid and about three inches long. Then, the sterno-cleido-mastoid and the carotid sheath being drawn to the outer side, and the omo-hyoid and the larynx towards the median line, the section was carried down to the prevertebral space. Some trouble was experienced from the thyroid gland, which projected upwards to a level with the cricoid cartilage. It became necessary to cut around its upper edge and turn it down, the left superior thyroid artery being cut in so doing and tied. A bougie was then passed into the œsophagus by Dr. W. H. Thorndike, and an incision into the œsophagus made upon it. Then, the bougie being withdrawn, Dr. Cheever passed his forefinger into the wound and explored the œsophagus below, the finger reaching beyond the level of the sternum. Nothing could be found. But on turning the finger upwards, a foreign body was detected, behind and between the arytenoid cartilages lying obliquely, presenting a free end to the left side. After a good deal of ineffectual effort with finger and forceps, this was dislodged by the finger passed down from above through the mouth, meeting the fingers of the other hand passed upward from below through the wound. It was removed through the œsophageal wound in the neck and proved to be a fish-bone, one inch and three quarters long, about one eighth of an inch in diameter, with ragged ends. The operation lasted about an hour and a half and was greatly impeded by the patient's dyspnea, his throat being frequently obstructed by mucus, which collected in large quantities.

The patient recovered readily from ether and was put in a room by himself, which was kept full of steam, in the charge of a special nurse night and day. The wound was left open, with a single thickness of gauze laid over it; ice-water dressing. Nothing to be given by mouth till ordered. Hands and feet to be bathed in cool water to relieve thirst. Ice to be held to lips to moisten them. Ice-cap to head.

R Beef tea or egg nog . . . . . 3iv.

Brandy . . . . . 3ss.

M. et S. To be given per rectum every four hours.

Evening temperature 101.6° F.; pulse 98; respirations 25. Was somewhat restless during the night, but otherwise as well as could be expected.

*Wednesday.* — Morning temperature 103.1° F.; pulse 125; respirations 40. Patient complained much of thirst, but was perfectly obedient to orders and of good courage. At eleven a. m. was raised in bed by Dr. Cheever and given a drink of water. It excited such a spasm of cough and expectoration that the giving of nourishment by the mouth was farther postponed. His condition remained about the same through the day, evening temperature 101.6° F.; pulse 112; respirations 48. Was given a quarter of a grain of morphia sulphate by suppository at night and slept fairly.

*Thursday.* — Morning temperature 100.7° F.; pulse 125; respirations 36. During the morning he was

<sup>1</sup> Read before the Suffolk District Medical Society, February 18, 1882.

given a tumblerful of milk, which he drank with comparative ease, but little escaping through the wound. He was then ordered to have four ounces of milk every two hours by the mouth, the enemata, however, to be continued and the brandy in them to be doubled, making an ounce every four hours, as at this time the action of the heart and condition of the pulse at the wrist were rapid, dicrotic, and rather feeble. Patient remained comfortable during the day. Evening temperature 102.5° F.; pulse 96; respirations 46. At six p. m. Dr. Cheever saw him again and directed two drachms of rum to be added to each tumblerful of milk he swallowed. At this time he was given ten minims of tr. digitalis, and this was repeated six hours later. There was some diarrhoea, and some inability to retain the enemata, and they were reduced to once in six hours and five minims of tr. of opii ordered to be added to each. He took, however, but one enema containing laudanum, as to the enemata given at twelve fifteen grains of chloral hydrate was added instead. During the evening a quarter of a grain of morphia sulphate was given by suppository. At nine o'clock the pulse had much improved, was 110, of good strength, much less irregular. After this he was given milk every hour if he asked for it. About one o'clock the house-surgeon, Dr. R. A. Kingman, was called by the nurse, who had noticed a change in the breathing. The respiration was rapid, with tracheal rales. Pulse of good strength, rapid, slightly irregular. Patient was perfectly conscious. Half an hour later there was no change, but in a few minutes the respiration grew more shallow, more rapid, irregular, and soon ceased. There was no change in the pulse. Five grains of ammonium carbonate were given hypodermically without any effect, and death occurred at 1.40 A. M. Friday, about sixty hours after the operation. An autopsy was applied for in vain.

### CHRONIC HYDROCEPHALUS; PERMANENT ANTISEPTIC DRAINAGE.<sup>1</sup>

BY H. C. HAVEN, M. D.

This case is reported on account of the novelty of the method of operation employed by Dr. Bradford.

S. H., aged two years, entered medical wards at Children's Hospital July 4, 1881. Mother says he has had water on the brain since three weeks of age. Head has gradually increased in size. Has occasionally had convulsions, screaming, and foaming at the mouth; these convulsions were especially noticed when the child was held up or carried about. Has been tapped by Dr. Marion, the family physician, three times; mother thinks child intelligent, but admits his inability to express any wants.

On entrance: child well nourished, but anæmic. Skin very dark, approaching a bronzed hue. Shows no signs of intelligence; does not notice objects or a bright light; laughs occasionally in a vacant manner; tosses arms and legs about continuously.

<sup>1</sup> Read before the Suffolk District Medical Society, February 18, 1882.

Patellar reflex apparently normal; abdominal and cremasteric reflex absent.

After entrance cried continuously, and had a slight convulsive attack. The cry was so loud and continuous it was necessary to give morphia 0.002, or  $\frac{3}{32}$  of a grain, p. r. n.

Bowels constipated, and remained so throughout.

The eyes were examined by Dr. C. H. Williams, who reported discoloration of discs, with apparent loss of retina; vessels smaller than normal.

Iodide of potash was ordered, but discontinued in a day, the absurdity of medical treatment being most patent, and the case was transferred to the surgical side, where it came under the care of Dr. Bradford.

July 15th. Dr. Bradford inserted a trocar in the large fontanelle, just outside the median line, and a little behind the coronal suture; without pressure 100 cu. cm., or about three ounces, of clear fluid flowed. The patient became very pale, respiration fell to eight, pulse almost imperceptible; this state of collapse continued for some minutes, the patient lying quite motionless. After the operation the fontanelle was noticeably flattened; the reflexes not affected. Considerable fluid leaked away; soaking three towels the first day, two the second. The next day, July 16th, he seemed better; he ate his dinner with apparent relish.

July 18th. Nurse reports him much quieter than before tapping.

July 22d. Dr. Bradford inserted trocar in about same locality, with rigid antiseptic precautions (spray, etc.); 75 cu. cms. of fluid escaped. Horse-hair drainage inserted, and head inclosed in gauze and cotton dipped in thymol solution, oil-silk covering over all. During this operation tonic spasms of lower extremities and clonic of upper were present. An hour after operation pulse 144, respiration 30.

July 25th. Horse-hair drainage and antiseptic dressings removed; no fullness of fontanelle.

July 26th. Considerable serous discharge. Patient seems more natural; looks better; takes food with less reluctance; sleeps quite well. For two days after the operation the diapers were stained with a markedly blue urine.

July 27th. Child seemed as usual during the morning; took nourishment freely. About three p. m. had clonic convulsion of right side, becoming tonic, and lasting half an hour. Three successive convulsive attacks, at intervals of half an hour, all limited to the right side, ensued. Death closed the last at about six p. m.

#### REMARKS BY DR. BRADFORD.

The patient, according to the mother's statement and that of the nurse, was more quiet and appeared more comfortable after each tapping and while fluid was leaking from the puncture than after the cessation of this discharge, and the consequent accumulation of fluid and increased pressure.

Horse-hair drainage was tried (under antiseptic precautions) to prevent this increased pressure; it being thought that owing to the ossification of the cranial bones and the impossibility of a collapse of the skull the danger of too great discharge of the cerebro-spinal fluid would be avoided. From the appearance of the child there was no evidence of greater disturbance from the presence of horse-hair than from the previous tapping. The hair drainage was taken out as the child was to be removed from the hospital by its mother.

July 15th. Soon after operation respiration 8; pulse 64. July 22d. Blue urine. July 24th. Light troubles him. July 25th. Dressing and hair removed.

## RECENT PROGRESS IN INSANE ASYLUM MANAGEMENT AND CONSTRUCTION.

BY WALTER CHANNING, M. D.

### LUNACY IN ENGLAND.<sup>1</sup>

DR. ROBERTSON finds that, according to the Commissioners of Lunacy, there are 71,000 insane persons of whom they have cognizance in England. This would make the ratio of about one insane person in 350 of the population. In America, Rev. F. H. Wines, superintendent of a supplementary branch of the census of 1880, having the statistics of the insane in charge, estimates the total number at 100,000, though his returns give a smaller number. This would give us a ratio of about one insane person to 500 of the population. In the older States the number is greater, in Massachusetts, for example, being not less than one in 350.

There are sixty English county and borough asylums containing upward of 40,000 insane persons, each asylum varying in capacity from 250 to 2000. The average cost per bed has been about £200. The average weekly cost per patient has been, exclusive of interest on the cost of construction and yearly repairs, ten shillings a week.

The plan of placing persons of small means in large public asylums is commended. Mention is made of the effort of Mr. Dillwyn to obtain a law with this end in view. One very important reason for taking this step is that the cheaper private asylums are so poorly managed. That such is *not* the case in this country must be remembered. Our cheaper private asylums are the McLean, at Somerville, the Hartford Retreat, Dr. Kirkbride's, the Butler Hospital, at Providence, etc. These institutions are fully as well superintended,

and much more comfortable in regard to surroundings and food, than most public hospitals can afford to be.

Of middle-class lunatic hospitals, there are in England thirteen, excluding two idiot asylums. These asylums have about 3000 beds and the average weekly cost of maintenance is £110. They receive thirty-six per cent. of all the private patients. In one of these asylums (St. Andrews Hospital at Northampton) a saving of £10,000 was made last year. Dr. Robertson thinks that this kind of hospitals affords the best means of treatment for private patients, and in thirty years thinks they would pay back the cost of construction. They will be of course public asylums for private patients. There are 3400, or forty-three per cent., of private patients treated in ninety-six private asylums. Most of these have grown up under a bad system and should cease to exist, but there should still be private asylums which may exist by the side of the public middle-class asylums. Dr. Mitchell, Commissioner of Lunacy, takes the same view. Dr. Robertson is in favor of small asylums for four to six patients. In reading the English view of private asylums, it must be remembered that it is influenced by the unfortunate system which has grown up in England. Under this system lunatics have been taken of all sorts and kinds by all sorts of persons and kept for the sole purpose of gain. This system having been inaugurated many years ago when the public were glad to find any one who would shut up their relatives, it is easy to see that many abuses might arise. Human beings were dangerous animals to be shut up, and to be treated like dangerous animals — and they were. To-day, therefore, England is struggling to throw off this incubus which she has on her hands. In America we are more fortunate. Here private asylums have started simultaneously with the public hospitals, and the larger ones have in almost all ways had a public organization. Our small private asylum system is in

<sup>1</sup> Lunacy in England (or England's Irrenwesen.) An address by Dr. C. L. Robertson, Chairman Section of Mental Disease, International Medical Congress.

its infancy, and is yet almost too small to furnish care for an appreciable number of insane persons; it seems to be wanted, however, and is growing rapidly.

Dr. Roberson speaks strongly in favor of the care of insane persons in private dwellings, and thinks that one third of the present inmates of private asylums can be placed under family treatment with safety. The experience of Scotland and the opinions of Drs. Bucknill and Maudsley all favor this plan of treatment.

Dr. Lawson<sup>1</sup> takes advanced ground on this subject. In one variety of cases, delusions and delusional methods of thought are superadded to the substance and methods of ordinary idealism and rarely we find here cases of real danger. In another variety, the workings of the mind become altogether delusional and here the abnormal elements and modes of thought virtually abrogate those which are normal, making the patient dangerous to himself and others by the supremacy of his mental aberration over his daily conduct. The first class are the most common, and it is only the second class that require care in an asylum. Residence in an asylum is apt to make a patient with mania, or melancholia, attended by suspicion, worse rather than better. A maniac of this class is only too ready to find in the expressed delusion of another the most satisfying conviction of the truth of his own fancies. In cases of recurrent mania also, Dr. Lawson has seen most excellent results from treatment in private dwellings.

#### IMPROVEMENT IN ASYLUM MANAGEMENT.

The Scotch Commissioners state at some length in their report the changes which have in recent years taken place in the management of their asylums. These changes have been in three directions, as follows: (1) In the greater amount of liberty accorded patients; (2) in the increased attention that is devoted to their industrial occupation; and (3) in the more liberal arrangements that are made for their comfort. As an example of the first change may be mentioned the abolition of airing courts. It used to be thought that an intensely excited patient could work off his excitement with safety in an airing court. But it was found that the quieter patients were irritated and made worse by association with such a patient. By placing patients in the companionship of judicious attendants, and allowing a wide range of the grounds, the results were better. So with the "open door system." Here again a patient was found to be better satisfied when he felt that the doors were unlocked and he could go out at will. The relations of an attendant to a patient assumed then less of the character of a jailer and more of the character of a nurse. Experience proved that a very much larger number could be trusted than had been supposed.

An immediate effect of thus removing restrictions was a renewed desire to take up some occupation, and this led to earnest study on the part of superintendents. It was found that a great variety of industrial pursuits were needed — of these, farm-work offered the greatest advantage. Here every grade of work, from simple spading to the elaborate care of flowers, could be found. The estate could be improved; there would be road-making, embanking, draining, fencing, plowing, digging, wheeling, and even building; in short, a little of all kinds of labor could be introduced. For one patient who would be stirred to ra-

tional reflection by such a thing as a picture, twenty ordinary inmates of asylums would be so stirred in connection with the prospects of the crops, the points of a horse, the growth of the trees, the sale of the pigs, etc. Very much was accomplished, too, in the way of providing work for female patients. Before these persons had often led idle lives in the wards, but gradually they also were stimulated to work.

To inaugurate these and other changes considerable courage and boldness on the part of the superintendent were necessary. "The superintendent who really takes most precautions against violence is not the man who applies the most complete restrictions on liberty, but he who weighs the general results of different modes of treatment and selects that which in practice proves most successful in decreasing the number of violent acts. . . . We cannot hope, in carrying out any system, to exclude the effect of mistakes in judgment and neglect of duty."

In America we do not, by any means, find that we have advanced to the position now occupied by Scotland in the treatment of the insane; perhaps we can never hope to reach the same point, as the conditions under which we work are different, but notwithstanding, very important progress has been made. At Danvers, for example, we find that unlocked wards are being tried on quite a large scale.<sup>2</sup> Dr. W. B. Goldsmith, the superintendent, says that the doors of five wards have been unlocked throughout the year, giving over one hundred patients (about one sixth of the whole number) full freedom of the hospital farm. Only five escapes occurred among this large number. Occupation was furnished for as many as possible, but owing to the small and badly arranged laundry only a comparatively small number of females can be employed. A new laundry building seems to be needed. If such is built it is to be hoped that the European fashion of having the washing done chiefly by hand will be followed. Under some circumstances it is an excellent thing to do all the laundry work by power machinery, but in a large asylum it is taking away the best form of occupation for a large number of the healthy, able-bodied, but demented or careless and unskilled female patients.

Under the head of attendants Dr. Goldsmith brings into view the *bête noir* of American asylum management. He employs sixty-three attendants; during the year there have been fifty-nine changes. Seventeen were discharged for cause. Such frequent changes "preclude the possibility of perpetuating an efficient organized system of training for attendants." On the attendants, principally, the success of the "open-door system" as well as the system of non-restraint depends. In England attendants are in service for many years, and with the sharp social distinctions can be much better disciplined than here, and they can be looked to for more intelligent cooperation. I do not, however, mean to say that attendants are perfect in England, or that the average in this country, considering the sources from which they come, are not better than would be supposed.

Perhaps the Government Hospital for the Insane at Washington, D. C.,<sup>3</sup> furnishes as good an example as any of the improved system of hospital treatment in many respects. At this hospital there has existed for a year past a continuous medical service during the

<sup>1</sup> Report Scotch Commissioners in Lunacy, 1880.

<sup>2</sup> Annual Report for 1881.

<sup>3</sup> Annual Reports for 1880-81.

entire twenty-four hours. As far as I am aware, this is an innovation on the usual medical system of management. The total insane population of the hospital is over nine hundred. With such a large number a considerable amount of night work was necessary, and with the terrible fire at Anna, Illinois, in view, it seemed to the hospital management that an efficient night medical officer might relieve the rest of the staff of arduous labor, and in case of an accident perhaps be the means of preventing serious disaster. The experiment has worked, so far, well, and probably has already saved several lives.

At this hospital during February (a month, of course, unsuited to farm labor) the superintendent, Dr. W. W. Golding, states there were employed, out of 706 males, 188. And out of 237 females, 97. In weather suitable for cultivation the number employed would exceed thirty-three and one third per cent. on the whole number. For females alone the percentage is about forty-one for February. The women work with the needle and in the domestic department. The men work at brush making, mattress making, hair picking, tailoring, stable, domestic labor, farm work, road building, etc.

The "open-door" system applies to more than one fourth of the male patients. In one cottage building there are sixty-five inmates and no window guards. In another two hundred patients and no guards on the lower floor, and very slight ones to prevent accidents on the upper stories. The doors of these buildings are unlocked, and patients can go from one part to another at will. Only one escape has so far occurred.

These figures may seem small to our Scotch and English brethren, but they show that some of our asylums are at least following in their footsteps. It must be remembered that the Government Hospital has a large proportion of negro patients, and among them many violent and difficult persons to manage.

#### HOSPITAL CONSTRUCTION.

In this direction, also, progress has been marked, for we find smaller buildings, better adapted to the needs of the patients, being erected, and at a very much diminished cost. At Washington the Relief Building connected with the Government Hospital for the Insane cost only two hundred and fifty dollars per patient, furnished.<sup>1</sup> This is a low estimate for the present high price of materials and labor, but five hundred dollars per patient would build and furnish a comfortable building for at least mild cases. At Kankakee, Illinois,<sup>2</sup> there is to be a small central building for acute cases and officers. There are then to be in addition cottages, as many as may be needed, and to contain from twenty-five to thirty patients. These cottages will be two stories in height, having day rooms on the lower floors and dormitories on the upper. They will be located on the streets, into which it is intended that the grounds shall, like a village, be divided. It is intended that these cottages shall be the permanent home of a chronic class of patients.

The managers of the Vermont Insane Asylum have recently purchased a boarding-school estate and building near the asylum, at which a suitable class of patients will be treated.<sup>3</sup> At Hartford a cottage has been erected by a gentleman for his insane daugh-

ter. This will eventually be used for other patients.<sup>4</sup>

As a result of the fire at the Illinois Southern Hospital for the Insane, at Anna, in April, 1881, it was found necessary to put up a temporary structure while rebuilding was in progress.<sup>5</sup> A one-story building, consisting principally of one ward on each side of a centre building, was found to answer the purpose admirably. There were numerous doors into large airing courts, which were kept open so that patients could wander out at will. The greater amount of freedom in this building had the effect of making the patients more contented, and they improved in health, and less restraint was necessary. At night, though large numbers were together, they were unusually quiet. This building worked so well that it will be used in the summer in future. Its cost, including hot and cold water and a system of sewerage and gas-light, amounted to only thirty-seven dollars per capita.

Dr. Bancroft<sup>6</sup> argues that patients should not be placed promiscuously together in the wards of an asylum, but in buildings especially adapted to their needs. "The great diversity of demand in the persons coming under asylum care and treatment, growing out of wide differences in temperament, forms of disease, natural tastes, and other circumstances, calls for a corresponding variety in situation and the influences needed to meet in the best manner the wants of the whole." There is always an important minority who do not require the amount of repression needed by the majority. There should be no radical departure from the customs of society unless necessary. General customs should be followed until disease renders a change imperative. The plan of varying the surroundings to suit the patient's case has been extensively carried out at the Morningside Asylum in Scotland, and at Cheddle in England. In these institutions all forms of insanity are treated, and every kind of building, from the close asylum to the common dwelling-house, is found. At Cheddle there are eight or more houses, and two at the seashore. Probably about one fourth of the patients live in these houses. One indirect result of adopting this modified plan of building will be to diminish the contrast between life in the institution and ordinary domestic life, and thus make the public less unwilling that their friends should be placed under treatment. There is now a very natural feeling of dread when one is called on to place a dear relative among a mixed mass of insane persons, to be completely deprived of liberty, and subjected to an annoying and often unnecessary discipline. By procrastination in treatment very valuable time is lost, and hence any changes which will bring the patient earlier under treatment will be a step in the direction of more frequent recovery.

#### PROVISION FOR INSANE CRIMINALS.

During the last year there has been renewed interest felt in this subject, and in Massachusetts, perhaps, more than elsewhere. This has been partly caused by the murder of the President, and the question, What shall be done with "cranks" of the Guiteau type? But in Illinois, New Jersey, and our own State, for example, the trouble caused to the insane asylum man-

<sup>6</sup> Address of the superintendent, Dr. J. Draper, before the New England Psychological Society.

agers by the large number of insane criminals under treatment has led them to a vigorous discussion of the question on their own account. In Illinois we find that an asylum for insane convicts is already under way on the State Prison grounds.<sup>1</sup> In New Jersey but little progress has been made. In Massachusetts progress has been made—in talking at least. The trustees of the State Insane Hospital at Taunton call attention to the law of 1874, providing that provision should be made for insane criminals in the new hospitals at Worcester and Danvers, and at the new State Prison in Concord.<sup>2</sup> That such provision has not been made they infer from the fact that none have been withdrawn from their hospital, but, on the contrary, they have increased in number until there are now twenty-seven. They say the subject is so important that it demands definite action. At the Worcester State Insane Hospital Dr. J. G. Park, the superintendent, states<sup>3</sup> that eleven convicts have been received from the State Prison, three females from the reformatory, and three men from Deer Island. Of a transfer from Taunton, two were from the State Prison, and six from the House of Correction. Ten men and one woman were received from jails and houses of correction. Here there are altogether thirty-six persons belonging to the criminal class, in one year entering this hospital. Probably some of them could be treated in an ordinary asylum, but the larger part should receive separate treatment in a special institution. Dr. Park thinks there is not a lunatic hospital in the State suitable for the safe custody of the criminal insane as a class. He would have the plan for their separate treatment include provision for dangerously homicidal patients who are not criminals. Some doubt might exist as to whether it would be constitutional, or, indeed, advisable, to treat with criminals persons of any other class.

The Massachusetts Legislature of 1881 passed a resolve requesting the Board of Health, Lunacy, and Charity to prepare a plan for separating insane criminals from the other insane in the public asylums. In their last Report the Board gave the results of their investigation of the subject.<sup>4</sup> The chairman of the Lunacy Committee, Dr. Edward Hitchcock, visited the English Criminal Lunatic Asylum at Bracknell, known as the Broadmoor Asylum, where he found five hundred and thirty-two patients. This institution has a prison-like appearance, and the clanking of keys and creaking of iron-grated doors are suggestive. There are numerous workshops, and the patients are allowed a small sum of money for good work and behavior, but it is a prison, and a very rigid one at best. The Earl of Shaftesbury, for fifty years or more connected with the English Lunacy Commission, warned Dr. Hitchcock against making an asylum so comfortable that convicts would be glad to be transferred to it. Shortly before, at a county asylum, a patient murdered a visitor in order to be transferred to the "farm," as Broadmoor is known to the convicts. On the whole, the English Lunacy Commissioners seemed satisfied with their method of treating insane criminals in separate institutions.

At a later period of the year, Dr. Hitchcock, Mr.

F. B. Sanborn, and the writer visited the Criminal Insane Asylum at Auburn, N. Y., at the request of the Board. At this asylum there were at the date of the visit one hundred and forty-two patients. This small number of inmates for a State of over five millions is explained by the fact that the period of detention of patients is short, and that there are, according to the statement of the superintendent, Dr. C. F. MacDonald, probably several hundred insane criminals scattered around through the State who would be fit subjects of treatment in the Auburn asylum. Dr. MacDonald thought that were the laws modified the number in his asylum might rise in a few years to five hundred. This asylum does not have a prison-like appearance, resembling closely the ordinary asylum, but convicts rarely feign to get in, and do not stay long if sane. Comfortable food and surroundings, and thorough medical care seem to exert a good effect on the inmates. The discipline is good, the amount of restraint one per cent., and the number of cures fully equal to that of Broadmoor. Hence it may be inferred that the asylum plan, rather than the prison plan, may be the more successful in America.

Drs. Orange and Nicolson, medical officers of Broadmoor, find a marked difference between convicted and unconvicted insane criminals, so that they would prefer a separate institution for each class.<sup>5</sup> In this country, so far as a smaller experience goes, while there is a difference in some cases, it is not so great as to call for distinct institutions for the two classes for some time to come.

The Board find three varieties of the "criminal insane," as they call them. First. There are those insane persons who have committed crimes, and have been adjudged lunatics by the court. Second. Those persons who have become insane in prison. Third. Persons obviously insane, and confined in asylums, who either commit offenses there or manifest such dangerous tendencies as to render them unfit for association with the ordinary insane. This class is, perhaps, more in need of separation than the others. As I have said before, I doubt the propriety of making these persons into criminals until they have committed a crime, making them properly amenable to the law. Perhaps the law could be so modified as to bring them within the desired category, for they are a troublesome class.

A certain number of the "criminal insane" can, under proper circumstances, be sent to an ordinary asylum for treatment, the Board thinks. There will be occasionally persons of good social standing, of upright character, and high attainments, who may have through insanity committed a crime. These persons, if any, can be made an exception.

The Board then goes on to propose four plans for separation from which the legislature can choose the best. The first plan is to take the eastern part of the State Reform School at Westborough, which is strongly built for prison purposes, and, tearing out the cells, adapt it to the purposes of a criminal asylum. This arrangement would allow room for one hundred insane criminals, with quarters for the necessary officers and attendants, and would cost about thirty thousand dollars. By adapting other portions of the buildings room could be found for about one hundred and fifty more patients of a more manageable class, epileptics, for example. A second plan is to build a "prison asy-

<sup>5</sup> A Chapter in the History of Criminal Lunacy in England.

<sup>2</sup> Annual Report, 1881.

<sup>3</sup> Annual Report, 1881.

<sup>4</sup> Third Annual Report of the State Board of Health, Lunacy, and Charity.

lum" in connection with the State Prison. It seems quite feasible to use a portion of the prison, remote from the main prison, for the convict insane. There is also a space of four acres inside the prison enclosure where a building for one hundred insane persons could be erected at a cost of less than seventy-five thousand dollars. A third plan is to use certain wards connected with some State insane hospital where the insane criminal patients could be placed together. A fourth plan is to build a new and distinct asylum, which would cost from one hundred and fifty thousand dollars to two hundred thousand dollars, for one hundred and fifty persons.

The Board would on the whole give the preference to the first plan, and they add that the Westborough buildings could at a future time be used for some other class of the insane. The experiment would not cost much and the buildings could be got ready in a very short time.

It may be said, in considering these plans, that nearly all hospital superintendents, and others acquainted with insane criminals, would regard the fourth plan as the only one which, on scientific grounds, would be the most successful.

We find from the Report of the Board that our State will very soon be called on to provide room either for our chronic insane, who are more than nine tenths of the whole number, or for the recent and possibly curable insane. Now the question is: Will it not be better to use Westborough and its large farm for this great number who must be provided for within a year or two, rather than spend money on it for the benefit of a comparatively small number of insane criminals? We find that cottages can be built at Westborough, and at a cost not to exceed \$200,000; the Report states there will be room enough for five hundred chronic insane persons.

The best course would be to appropriate money for this change, as well as a moderate sum to begin a criminal asylum; should the legislature refuse, however, to do this, it will then undoubtedly be advisable to adopt Westborough for the criminal insane.

#### PREVENTION OF INSANITY.

Dr. Mary Putnam Jacobi has made a suggestive and interesting study of this subject.<sup>1</sup> She regards the three great elements in the moral substratum of a person predisposed to insanity, as first, the egotistical predominance of the instincts over the faculties of reflection and external relation; second, the ineffectiveness of the will even when this is impulsive, or violent; and third, the inaptitude for ideas resulting in their poverty and imperfect combination. To overcome these defects we need a strenuous educational system. "The acquisition of knowledge, the training in morals, the formation of habits of thought, must all be centred on practical activities. . . . In minds predisposed to insanity there is often, perhaps always, a marked deficiency of elasticity. An impression sinks and remains; the mind cannot disengage itself, or recover its tone; it cannot pass quickly enough into the contrasting mood; a capacity to do this is the natural provision against strain; it probably corresponds to a law of rhythmic action in the physical mechanisms of thought. This capacity should therefore be carefully cultivated

by encouraging alternations of attention on the first sign of fatigue. . . . Irritability always means the tension of nerves overcharged with impressions, which can find no issue in movements or actions. Movement is the physiological remedy for irritability. It is the remedy sought by nature in the higher grades of irritability, where the patient is no longer conscious of the tension, in maniacal excitement and mania."

The question of occupation is the great question of moral treatment of insanity. A new world should be built up around the patient. Palliation of symptoms is of great importance. The mere continuance of a morbid function may result in collapse by destruction of its mechanism.

The above examples give a slight idea of the accuracy and clearness attending this study of Dr. Jacobi. Though the writer may not agree with her in all her conclusions, he cannot help calling attention to the power of analysis she displays. It is to be regretted that want of space prevents a fuller abstract of the paper being given.

### Hospital Practice and Clinical Memoranda.

#### UNUSUAL OR ACCIDENTAL RESULTS OF VACCINATION.

BY ALFRED H. HOLT, M. D.

ONE of the principal arguments of the advocates of anti-vaccination is, that the operation is liable to introduce into the system some other disease than the one intended, or that the process it sets up may develop or set going a train of events more injurious than the disease it is intended to modify or prevent. However unsupported or absurd such a doctrine may be, its general discussion by those in the community who know nothing of the facts of the case has brought the people generally to look upon vaccination with great distrust, and a large part of them are constantly on the watch for some bad result to follow in those who have had the operation. When such a state of things exists it is certainly of the greatest importance for not only physicians, but the community at large, to know just what results are liable to sometimes follow vaccination when properly done. For this reason I relate the following cases. As far as I can learn by reading and inquiring none like them have heretofore been recorded.

December 3, 1881, a woman was removed from a house on Harvard Street, Cambridge, to the small-pox hospital; she was, at the time of removal, at the sixth day of the disease and at the fourth of the eruption. Her two children, one four and the other six, who had been vaccinated, had been constantly in the room with her, and up to the last night had slept in the same bed. These children and the other inmates of the house were at once vaccinated, and instructed to remain here that they might be under observation. Nine days after Dr. Turner, Assistant City Physician, and myself saw them. The girl, four years old, was sick in bed, with quick pulse, hot skin, flushed face, and some headache. She had two well-marked and in every way characteristic vaccination pustules on the arm. The boy, six years old, was about the house, although the vaccination had taken full as well as his sister's. The next day, or the tenth of the vaccination, I was called

<sup>1</sup> The Prevention of Insanity and its early and proper Treatment. A paper read before the American Social Science Association, September, 1881.

in great haste by the woman who had charge of the children to see the girl, she thinking she had the small-pox. I found that she had passed a restless night and that toward morning an eruption appeared which soon covered the face, body, and limbs. This eruption presented very much the same appearance as the so-called German measles; it was of a dusky red color, a little raised above the healthy skin, and was distributed in irregular patches; some of those on the body were as large as the palm of the hand, while those on the limbs, hands, and feet were smaller. The eruption covered at least seven eighths of the surface, it was a little rough to the touch, and with a lens there could be seen scattered over the patches a very few small cup-shaped vesicles. The temperature of the girl was a little elevated and she still complained of headache, but did not appear very sick. I saw her the next morning; she had passed a good night, sweating rather profusely in the last part of it. She was sitting up in bed playing, and was hungry. The eruption had faded a good deal and was much less elevated. The next day the eruption had wholly disappeared except that it had left a brownish tinge of the skin which also was gone in a day or two.

The next case was in a girl sixteen years of age who came from the British Provinces and had never been vaccinated. The ninth day after vaccination she had a slight headache, and that night was kept awake by an intolerable itching of the body and limbs; in the morning it was discovered that she was covered with an eruption. Dr. Turner was called, and at his request I saw her in the evening, when she presented the following appearance: the skin was dry and hot, the pulse quickened, and the temperature a little elevated, but she did not appear much sick; the eruption was much like that described in the first case in color and distribution, but was much more elevated and rougher to the look and touch; there were the same microscopic cup-shaped vesicles scattered over the patches, and some of the smaller patches themselves were more raised at the edge than in the centre. The next morning the girl looked bright, the skin was moist and she was improved in every way. The eruption was paler and less elevated. The next day, or the third after the full development of the eruption, it had disappeared, leaving the same brownish tinge to the skin observed in the first case. The vaccination had been successful and she had two well-marked pustules on the arm, which apparently were in no way modified either in their course or appearance by this eruption. The second time I saw this case I was requested by Dr. Turner to see two others, both in the same family: these children, aged respectively five and seven years, were primarily vaccinated twelve days before; the operation was successful in both of them and they had two pustules each, that in every way presented a normal appearance for this stage of the disease. Five days before one of the children, a girl, complained of not feeling well, and the next day an eruption appeared which, from the description of the father, was like that in the two cases above described. This at the time I saw her had disappeared, except there was a large, but not elevated, patch on the right cheek; the skin of the body at the site of the eruption had the same brownish tinge, while that of the face and arms was dry and cracked, and in many places peeling; this did not occur in any of the other cases. The eruption appeared on the other child a day later, and when I saw him it

had disappeared, leaving the same appearance of skin observed in the other cases. I am informed by Dr. Turner that he saw one other case, in a girl, primarily vaccinated at the same time these children were. These vaccinations were all done by Dr. Turner and myself and with the animal virus sold by Codman & Shurtleff.

As will be seen, all of the cases occurred in primary vaccination, all of them about nine days after a successful operation, and all ran through about the same course.

I am well aware that no definite conclusion can be drawn from so small a number of cases, but from the facts presented I think it a reasonable presumption that this eruption was in some way brought about by the vaccination. If such is the case and this result is going to occasionally follow vaccination with animal virus it is highly important that the fact be known.

As I have said at first, so far as I know, no such cases have been before described. They are certainly very different from the cases of vesicular eruption, described by Flint and other writers, that sometimes follow vaccination. I have seen a case of this kind within a week and there is no resemblance by which one could be possibly mistaken for the other.

#### A CASE OF OESOPHAGOTOMY, WITH FATAL RESULTS.<sup>1</sup>

The reader also spoke as follows:—

This patient, formerly a seafaring man, had of late been engaged in bar-tending; and the confinement, together with the probable abuse of stimulants, must have impaired the vigor naturally resulting from his former mode of life. Again, he did not enter the hospital until the third day, and was therefore already much exhausted. It is probable that respiratory trouble existed at the time of entrance. Lividity of hands and feet and marked failure of the heart's action were prominent symptoms throughout the last two days of his life. It was thought that an abscess had already formed, as experience in similar cases and experiments on animals both showed this to occur, as a rule, on or before the third day. At the operation, however, no pus was found, but great oedema around the foreign body. On the second day after the operation he was able to take some nourishment. The pulse and respiration, however, steadily went up. Death probably resulted from pneumonia of a low type.

In these cases of oesophagotomy death occurs where the foreign body has been present for some time. The danger increases in direct proportion to the number of days elapsing before operation. In twenty cases collected by Dr. Cheever there were four deaths; first, pneumonia, operation fifty hours after accident; second, collapse of lung with gangrene of oesophagus, and inflammation of the stomach; third, operation,

<sup>1</sup> Vide page 265 of this number of the JOURNAL.

nine days after accident, retropharyngeal abscess; fourth, operation ten days after accident, retroesophageal abscess, opening into pleural cavity. Abscess or the burrowing of pus is the usual cause of death. The operation has been done five times at the City Hospital with one death; the mortality being the same, twenty per cent., as in the series of twenty cases.

The bristle probang was used in this case before the patient's entrance; it failed because the foreign body was entangled in the arytenoid cartilages. This instrument is usually effectual, so that the cutting operation is of rare occurrence. The cases of foreign body in the oesophagus may be divided into three classes:—

(1.) The hysterical patients, who imagine the trouble where it does not exist, or, if it has existed, has passed away.

(2.) Those where the body may be removed through the natural passages.

(3.) Those where it is necessary to cut for it. These cases are rare; and, as has been said, the chance of recovery bears a strict relation to the time elapsing before operation. Secondary changes are very apt to be present after the third day; either pus formation or pneumonia.

In reply to a question by Dr. Hodges as to whether there was any theoretical or practical objection to feeding the patient through a soft bougie catheter introduced into the oesophageal wound, Dr. Cheever said he had no personal experience in the matter, but had seen a case reported where this method was adopted. In this particular case he thought the objection would have been the laryngeal spasm, which might have been increased. The patient, also, is usually able to drink on the second day, although a slight amount of fluid may escape by the wound. Again, we know that a patient can if necessary be amply nourished by rectal alimentation. A case has been reported where the wound was closed, and food introduced through a stomach tube; Dr. Cheever thought it better to leave the wound open, as the formation of abscess is the one thing to dread, and this gives the best chance of avoiding it by insuring perfect drainage. Another objection to the introduction of a tube into the wound was the mechanical difficulty, for the walls of the oesophagus being naturally in contact the introduction is not an easy thing. This might be avoided by stitching a long thread into either side of the oesophageal wound so that they could be drawn apart; this, however, might be a source of irritation. Dr. Cheever thought if the patient were greatly enfeebled, that it might be of considerable advantage to leave a soft tube in the wound for administering nourishment, which could be withdrawn when the patient had made a good start towards recovery.

Dr. MARCY asked what was considered to be the cause of the pneumonia in these cases, the laryngeal spasm, or the introduction of foreign matter into the bronchi.

Dr. CHEEVER thought it due either to the laryngeal spasm, or, on account of the intimate relation of the voluntary and sympathetic nerves of the neck, to defective innervation of the lungs.

Dr. H. C. HAVEN reported a case of

CHRONIC HYDROCEPHALUS, PERMANENT ANTISEPTIC DRAINAGE.<sup>1</sup>

Dr. H. J. BIGELOW spoke of a thin spina bifida he

had tapped many years ago, allowing the fluids to drain off through several punctures made with a drawing needle; the child died in convulsions in about eighteen hours. Seeing that it was essential to guard against the escape of the fluid, he operated in three other cases by first tapping the cyst and allowing it to collapse partially in order to wind a cord tightly around the base of the tumor and outwards for an inch; a pedicle was thus formed in which there was room for the adhesion of the serous surfaces. All of these three infants had convulsions; one died; two recovered. There was left at the site of the tumor only a pedicle or stump. But it is a question whether it is desirable to prolong the life of a child affected with spina bifida even if it be possible.

Dr. M. H. RICHARDSON asked if the reason was known of the blue color of the urine.

Dr. BRADFORD replied that it had not been possible to gather enough for examination. The color had been noticed on the diapers. It was not due to carbolic acid, for that was not used; it was probably due to some disturbance in the nervous system.

Dr. R. M. HODGES spoke of the experiments formerly instituted by Magendie, which demonstrated that the cerebro-spinal fluid could not be removed without fatal results. Yet in fracture of the base of the skull we often find it escaping from the meatus auditorius or elsewhere in considerable quantities without apparent serious result. Dr. Hodges cited one case where a large enough quantity was collected from the meatus for a chemical examination to determine the point as to whether it was the cerebro-spinal fluid.

The CHAIRMAN also spoke of the case of an epileptic girl, in whose vertex there seemed to be a depression of the bone. He determined to trephine. On cutting through the skin and turning it back, and scraping away the periosteum, he punctured the bone, which proved to be very thin only, and not a depression. About a drachm of the cerebro-spinal fluid escaped; the operation was suspended, and the wound sewed up. The patient died in convulsions shortly after.

Dr. BRADFORD said in the case operated on by him the child was evidently so much better when the pressure was removed, although only a small amount of fluid was withdrawn, that he could not help feeling it would be rational to provide for the escape of the fluid earlier in any given case, and thus probably increase the chance of recovery.

Dr. CHEEVER spoke of the remarkable amount of cerebro-spinal fluid which could be secreted in a short time. A boy was brought to the City Hospital with a gun-shot injury to the spine; a number of fragments of the vertebrae were removed, and the canal was found to be opened; during the next twenty-four hours a large quantity of the fluid leaked away, saturating cloths constantly. He died the next day in convulsions.

#### TWO CASES OF SUCCESSFUL LITHOLAPAXY.

Dr. D. W. CHEEVER reported the following successful case of litholapaxy.

A gentleman aged sixty had suffered for two years from symptoms of vesical and rectal irritation; thinking that the tenesmus was the result of the piles from which he supposed himself to be suffering, he was operated on for prolapsed rectum with but slight relief to his distressing symptoms. Finding that he was comparatively comfortable while in bed, he remained

<sup>1</sup> Vide page 266.

there, and had been bedridden for some months when I first saw him. Rectal examination revealed nothing abnormal, vesical examination showed a stone; at the operation, two days later, it was proved to be a mulberry calculus, composed of oxalate of lime, about the size of a large horse-chestnut. The stone being very hard, and not having one of Dr. Bigelow's improved and more powerful lithotrites, I prepared to cut if necessary. The operation lasted *three hours*, the patient being deeply etherized throughout. Both the straight and curved evacuating tubes of Dr. Bigelow were used. There was scarcely any hemorrhage. As a matter of precaution demulcent drinks and hot poultices to the abdomen were ordered. The patient made an uninterrupted recovery; he was kept in bed two weeks much against his will. I have seen the patient since; he remains perfectly well.

I think this case worthy of record, as being a thorough test of the value of Bigelow's operation, the stone being so hard and the time of the operation being so long, yet the recovery was complete and speedy, no evidence of irritation remaining.

The man's life was undoubtedly saved by the valuable method of operating given to us by Dr. Bigelow, and his chance of recovery at sixty years, after lithotomy, would have been much less.

Dr. G. W. GAY reported a case of successful litholoxpy.

Mr. B., sixty years of age, had suffered for several years from frequent and painful micturition, resulting in loss of sleep at night, and inability to work in the day. For upwards of two years he had been compelled to pass water at periods varying from fifteen minutes to an hour and a half. Prolonged straining in these efforts had produced several large hemorrhoids, with some prolapse of the rectum. The urine was alkaline, cloudy, and scalded severely when passed. Numerous calculi, some of which were half an inch in length, had from time to time been evacuated. The patient was haggard, emaciated, and presented the appearance of having endured great suffering.

Two or more calculi were readily detected in the bladder with the Thompson sound. The viscous was so contracted that it seemed to contain but little else than foreign bodies.

June 4, 1881. The patient having been etherized, the calculi were crushed and evacuated by means of Bigelow's lithotrite and evacuator. The largest stone seized by the instrument was nearly an inch and a half in diameter.

We were an hour and forty-five minutes in removing eight hundred and forty grains (one and three fourths ounces) of phosphatic calculi. Considerable time was required in finding and seizing the last fragment, which was small, and easily floated away from the jaws of the lithotrite. The bladder was finally completely freed from the detritus, and the water returned nearly colorless. There was very slight hemorrhage at any time, much less, in fact, than is often met with in forcibly dilating a stricture of the urethra.

Convalescence was easy and rapid. There were no chills, fever, nor pain. The only opiate administered was given before he came out from the ether. The urine was tinged with blood for two or three days, when it became clear, and could be retained from one to three hours. Three weeks after the operation he was walking and riding about town, and was engaged in some light employment.

Our experience in this case taught us the importance of the principle laid down by Dr. Bigelow, which is that a stone should be comminuted, and *not* pulverized. We were unable to entirely avoid impaction of the lithotrite, but it is very much diminished if the male blade is not driven home, except when the instrument is to be removed from the bladder. A fragment having been seized, force is applied until the first resistance is overcome. That comminutes the stone. If the blades are forced together then the fragment is pulverized, and the jaws soon become so choked with *détritus* that it is not only difficult to seize and hold a stone firmly enough to crush it, but great difficulty may also be experienced in removing the instrument from the bladder.

As our patient had a capacious urethra we were enabled to use the evacuating tubes of No. 30 calibre, and found that the detritus came more readily through the straight than through the curved one, and by giving the former a cork-screw motion it was introduced with little difficulty.

We experienced no trouble from the bladder walls being drawn into the catheter, but we were delayed somewhat by fragments too large to enter the tube getting into and blocking up the opening. One piece in particular got wedged into the orifice, and not being able to dislodge it with the stream of water, we had some little difficulty in removing the tube. Such an occurrence could probably be overcome with a firm stylet without removing the catheter.

The slight amount of pain, hemorrhage, irritation of the bladder, and constitutional disturbance attending and following our operation was as surprising as it was satisfactory. It serves to establish the fact that the urethra and bladder are very tolerant of prolonged manipulation, provided that no foreign body is left behind to act as a constant source of irritation. It is a noteworthy fact that Mr. B., an old man, had been an invalid for years; he was entirely unfitted for business of any sort, and almost constantly suffering from the pain of an irritated bladder. He undergoes this comparatively safe operation; has a comfortable convalescence, and is practically well in a fortnight.

Dr. BIGELOW, in opening the discussion, said he had been much interested in the cases reported. Dr. Cheever's was a hard stone. Dr. Gay's a large one. The results which they had reported might be expected as a rule.

In reply to questions from Dr. Cheever as to how often it was necessary to slit the meatus, Dr. Bigelow thought the necessity to be only exceptional. If the meatus is small, and the operation is to be a long one, it is a convenient and harmless expedient; it is well to take a little care afterwards not to engage the mucous edge upon the catheter and strip it up.

Air in the bladder does no harm. The amount contained in the catheter is legitimately there. Beyond this amount no air can enter the apparatus unless from leaky joints. A little air is often as comfortably trapped for a time in the top of a large bladder as in the evacuator. The only harm the air does is to take up room which is better occupied by water if the bladder is not a capacious one. It is easy to remove it from the evacuator through a stop-cock and small hose at the top of the bulb, through which, also, the amount of water can be regulated.

Dr. MARCY asked how long cystitis lasted after the operation.

Dr. BIGELOW replied that it depended on the relation it bore to the stone; that is, if the stone were the disease, and the cystitis were dependent on its presence, it would be cured. If on the other hand there were a previous cystitis with enlarged prostate, and the stone were the result of these conditions, the relief, though often considerable, is partial. Cystitis with a large secretion of mucus is a troublesome complication. The mucus plugs the urethral orifice, causing painful tenesmus, until the tenacious mucus comes away in a mass, and the bladder is relieved.

In answer to further inquiries Dr. Bigelow said that perhaps the most difficult part of the crushing operation is picking up pieces behind the vertical wall of certain forms of enlarged prostate. As a rule the stone is easiest secured by pressing down the floor of the bladder with the heel of the lithotrite, which then occupies a pocket into which the stone gravitates, or by carrying the instrument well back, opening it, turning it to one or the other side, and closing it. A stone or fragment behind the prostate can be usually caught by depressing the floor beyond it, although if the perpendicular wall of the prostate is high it may be difficult to reach it even by inverting a short blade. One difficulty with the old lithotrite was the obliquity of the heel, so that when the crushing force is applied the stone is urged forward in the blades. The matter of clearing out an obstruction in the tube can easily be provided for by using an ordinary tin sound for the cavity of the straight tube. A curved tube sometimes gives more trouble, but can be freed by an elastic catheter. Any resistance, however slight, in withdrawing the tube should lead the operator to suspect a dangerously large fragment in the extremity of it.

In reply to a question as to whether Dr. Bigelow had ever known injury to result from nipping the walls of the bladder, he replied that he knew of one case in which he believed a fatal issue was due to that accident. In the ordinary instrument, with blades fitted at their extremities as accurately as forceps are, and with a female blade having no projection to keep away the wall of the bladder, the latter must often be seized. If only the mucous membrane were torn no serious effect might ensue, but if, in a thin bladder, the whole thickness of the walls were pinched he thought there must be danger. For this reason he himself felt easier in using his own instrument, which guards against this accident. The long female blade is especially useful to those not operating habitually.

In regard to the choice of a straight or curved tube, Dr. Bigelow thought neither was safer; the danger depends on the relation in size between the catheter and urethra. The tube, if large, must be introduced with great care, and with a perfect understanding of the anatomy of the parts, directing it downwards until it reaches the layer of fat lying between the urethra and the rectum, then coaxing it through the hole in the triangular ligament, and finally reaching the bladder by a corkscrew motion of the straight tube in the axis of the body. In only two or three cases had Dr. Bigelow found any trouble in introducing a straight tube. Sometimes the curved tube can be easiest introduced by hugging the pubes, and thus passing the upper instead of the lower part of the hole in the triangular ligament. The introduction of the straight tube is usually easier to the surgeon, but perhaps not quite so comfortable to the anesthetized patient. After the curved tube has entered the bladder the shaft occupies the urethra, and is of course straight.

Aided by the blackboard Dr. Bigelow described a some length the difficulties of attaining a perfect and convenient evacuator, and explained the faults of all those now in use. The question is one of physics, and involves the separation of air, water, and fragments in the most effectual way by the simplest means. He believed that he had at last devised a satisfactory instrument. To suppose that experiments to this end, out of the bladder, have no value is like supposing that the edge of a surgical knife can be tested only on the living tissues.

#### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MARCH 13, 1882. DR. J. C. WARREN presided.

#### ACUTE DISEASES OF THE LUNG.

DR. JOHN G. BLAKE opened the discussion on the treatment of acute diseases of the lung by saying that the prevalence of acute pulmonary diseases during our trying winter and spring months renders consideration of the subject at this time opportune. The variety under which these affections present themselves calls for an equal variety in treatment which shall be efficient, and appropriate to the pathological conditions; it requires special consideration of each particular case, and forbids any following out of routine. While varying but little in the later stages, the early manifestations and complications developing during the course of the disease differ materially in many cases, and when recognized in time assist in modifying or averting danger. Examples of this will suggest themselves to most present.

It may be of interest to compare notes in these exceptional cases, and learn from mutual experience which of the measures adopted in such emergencies are best. In our progressive profession the reliable remedy of to-day may be replaced by a new-found drug to-morrow, and in the search for improvement we are sometimes liable to be blown about by every wind of doctrine. Often the old means of relief is discarded for one whose scope of action it will require years to determine accurately. With the elders of the profession there is not much danger of this; they have been disappointed too often to fly by preference to every new remedy or method. *Experientia docet*: the physician of many years learns to sift chaff from wheat, and thus it is generally admitted that the older a man grows in practice the smaller becomes his *matéria medica*. It does not follow that his success becomes less, or his results not as satisfactory. He has by a process of elimination come down to the best of each class, and his patients receive the remedies only which time and experience have proved most reliable in obtaining the desired result.

#### PNEUMONIA.

Pneumonia, the most frequent of acute pulmonary diseases during the wet and cold season, and the most dreaded, of late years, by the community, offers a theme for careful consideration. Attacking all classes and ages, varying in its onset and complication, it affords occasionally opportunities for prompt action, which we should always be prepared to adopt. Venesection, that old remedy, the abuse of which in the past we have

heard and read so much about, is now reckoned, among the seniors, as one of the reliable helps they are unwilling to discard simply because it has become, from causes beyond its control, unpopular or unfashionable. That a practice which had rendered so much benefit to our predecessors, and which we are obliged to admit is so potent for good in proper cases, should have, within a quarter of a century, become so nearly obsolete, is one of the things it is hard to reconcile with common sense. Venesection might almost be reckoned among the lost arts, so rare has its use become, and notwithstanding the fact that its wise application in the treatment of special forms of disease forms the boast of some of our most successful and valued practitioners. Indeed, I doubt whether more than a dozen of my hearers ever performed or have any other than a theoretic knowledge of it. Yet any one who has seen its application in the early stage of sthenic pneumonia will admit that no remedy now in use is capable of accomplishing so much in affording present relief and future benefit. The objections to it are not easily stated nor very valid. The loss of a pint of blood, more or less, from the system when a vital organ is engorged is one that can be easily borne, and quickly recovered from. Its history in the past, showing the almost universal resort to its help in all cases that could be classed as purely inflammatory would certainly have been more brief had evil results followed. Every day experience of the effect of loss of blood from injuries or from natural processes is sufficient evidence of its harmlessness.

#### CONGESTION AND OEDEMA.

Congestion and oedema of the lungs, whether as a primary or secondary disease is sometimes met with. Perhaps no other condition is more dangerous if not promptly and actively treated. I know of no measure offering such prospects of successful results as speedy venesection. The following cases bear upon this point:—

A young man in Oneida Street, the subject of mitral regurgitant disease, was attacked with severe dyspnoea after unusual exertion and excitement. When I reached the house he was livid, almost foaming at the mouth, with labored and panting respiration. The lungs were full of moist râles, and the heart's action irregular. Here was a case calling for instant and decisive measures. I performed venesection, allowing the blood to flow until he began to feel faint. In a few hours he was decidedly better, recovered well, and is still living. I have always felt that the loss of blood saved him.

In the complications of Bright's disease we sometimes are met by alarming conditions resulting from pulmonary oedema, in which venesection may be relied upon to give prompt relief either as a first resort or after other measures fail. Such a case occurred several years ago at the City Hospital. Suffocation being imminent recourse was had to apomorphia to produce vomiting, which it did successfully, but ineffectually; stimulation, both external and internal, also failing, venesection was resorted to, and the patient saved for the time.

Dr. E. W. Cushing related to me a case of pneumonia in a young man in one of the Roman Hospitals, where bleeding was carried to fainting. At the time he considered this little less than barbarous, and intended writing home warning his friends against such practice, but he was greatly astonished on visiting the

place next day to find the patient up and about the ward.

Dr. Lyman, in case of sthenic pneumonia, a couple of years ago, bled with very marked effect in the early stage of the disease, at the City Hospital.

These cases are alluded to to indicate to some degree the class and variety which we may reasonably expect to relieve. Probably each member can recall occasions on which he regrets not having made use of the operation. In my own mind there is the memory of a pneumonia developing suddenly and unexpectedly after three days of intercostal pain, which had been unattended with physical signs of lung complication, and in which the marks of congestion, with livid lips, etc., were prominent. Dr. Bowditch, who saw the case in consultation, immediately advised venesection, but the husband would not consent. As the lady was not robust I did not urge the subject strongly, but under similar circumstances I would insist hereafter. The case terminated fatally.

When the acute stage is passed I am inclined to believe that the treatment best adapted to obtain good results is the so-called supporting treatment. A variable amount of stimulant, with milk, meat broths for nourishment, *ad libitum*, carbonate of ammonia and antim. tart. in small doses, varied according to age, strength, and severity of the disease, and jacket poultices or oiled silk, sheet rubber, or cotton-wool jackets, outline this method. Under such treatment the results of 1262 cases from the records of the City Hospital show eighty per cent. of recoveries. A glance at the table appended shows a wide divergence between the mortality of different years, 1873, for example, giving only three deaths in fifty-four cases, while 1880 has thirty-two in a hundred.

#### PLEURITIC EFFUSION.

In acute pleuritic effusion, where the symptoms were severe, I should aspirate without regard to the age of the effusion. I saw such a case with Dr. Gavin, of South Boston, where fluid rapidly collected, and the patient, a strong, vigorous teamster, showed dangerous symptoms. A gallon of serum was removed, and rapid recovery followed; no repetition of the operation was necessary.

I have been surprised to find this operation less frequently resorted to in chronic pleurisy, and that some physicians are of opinion that it often causes empyema. I think this idea erroneous if proper care is taken in its performance. We are all aware that the character of fluid in the thoracic cavity may be purulent from the beginning, and also that in a strumous constitution the change from serous to purulent may go on without operative interference as a cause. But while undoubtedly in a small number of cases there may be a change from serum to pus, I don't admit that the operation, in skillful hands and surrounded with proper precautions, is responsible for it. I fear that sometimes the manner of doing is more in fault than the simple withdrawal of the fluid. It is to be regretted that operators do not observe more care in the small details of antiseptic precautions. Experience shows that the more slowly the fluid is drawn off the less danger there is of distressing or dangerous symptoms following. In my own cases I use a small trocar, bright and clean, thoroughly washed in carbolic acid, and exercise only sufficient suction to draw off in a moderate stream, or simply to allow the fluid to run away through a tube, the

end of which is placed under water. I always terminate the operation when coughing or a sense of constriction and distress show themselves. With these precautions I can positively state that no bad result has attended or followed the operation in a single instance. This has been corroborated by Dr. A. L. Mason, in an examination of seventy cases in which the operation was performed a hundred and twenty times, in a paper he has prepared for the volume of City Hospital reports now in press. I quote his words: "The operation of *paracentesis thoracis* was performed one hundred and twenty times with no unfavorable result which could be attributed to the operation in any instance, but usually with great and permanent relief. The quantity varied from a few ounces to eleven pints." It is unnecessary to say that no death as the immediate result of the operation has occurred, nor have I been able to learn of any in private practice.

TABLE OF CASES OF PNEUMONIA.

|      | Total. | Died.   |
|------|--------|---------|
| 1865 | 13     | 2       |
| 1866 | 21     | 4       |
| 1867 | 26     | 6       |
| 1868 | 31     | 7       |
| 1869 | 58     | 3       |
| 1870 | 115    | 23      |
| 1871 | 59     | 16      |
| 1872 | 65     | 15      |
| 1873 | 54     | 3       |
| 1874 | 92     | 11      |
| 1875 | 79     | 25      |
| 1876 | 70     | 23      |
| 1877 | 82     | 16      |
| 1878 | 62     | 17      |
| 1879 | 80     | 25      |
| 1880 | 100    | 32      |
| 1881 | 135    | 33      |
|      | 1262   | 251=20% |

To sum up: I assume in the treatment of pulmonary diseases that (1) congestion of the lung, whether as a primary or secondary disease, is best treated by venesection; (2) sthenic pneumonia in its first stage demands the same remedy; (3) aspiration for pleuritic effusion is admissible at all times, and when properly done is not only harmless, but an indispensable means of shortening the duration of disease, and saving life.

These few remarks, echoing the opinions of Drs. Bowditch, Austin Flint, and other representatives of medical thought in this country, are simply intended as introductory to a general discussion of the subject, and are not intended either to indicate or limit the scope.

Dr. H. I. BOWDITCH said that although venesection had formerly been carried to an absurd extent, yet that physicians of the present day did very wrong to lay aside the lancet entirely; he then cited as instances of the early practice regarding venesection, a young anæmic woman who entered the Massachusetts General Hospital when he was house officer there, wishing to be bled, although she had previously been bled ninety-three times. Dr. Bowditch protested against the operation, but was ordered by the visiting physician to bleed the patient for the ninety-fourth time; also the case of a young, full-blooded man who came into his office with a request to be bled, as he

had been every spring, a proceeding which Dr. Bowditch refused to repeat. Dr. Bowditch then said that the time had come for our young men to take up the lancet and make a rational use of a most beneficial remedy, and he spoke especially of the relief given by venesection in those cardiac cases where there is great distention.

Dr. S. CAROT agreed with Dr. Bowditch that it was a pity that our young men did not use the lancet, and said that though rarely needed it was a most valuable remedy.

Dr. LYMAN agreed with Dr. Bowditch that venesection had been too much neglected, and spoke of the great relief experienced by him from bleeding during an attack of pneumonia which he had when he was a medical student. Referring to the subject of thoracentesis for effusion, he spoke of a case where, having decided to postpone the operation until the following morning, the patient died during the night. Dr. Lyman also said that he had almost always found that where a second tapping was necessary the fluid obtained was more purulent.

Dr. BLAKE thought that Dr. Lyman had been peculiarly unfortunate in his finding pus at the second tapping, and asked Dr. Mason to report the result of his investigation on the cases occurring at the City Hospital.

Dr. MASON stated that an analysis of two hundred cases of *primary* pleurisy at the Boston City Hospital, in a considerable proportion of which the fluid effusion was very large, showed that seventy, or about one third, required tapping. In twenty-eight cases the fluid was withdrawn more than once, and in six of these it became purulent. Cases of pyo-thorax were not included in the analysis.

Dr. KNIGHT said that he had never happened to see a man bled, but that he had no doubt that the idea of the reader was correct in a certain number of cases, especially in sthenic pneumonia, and that the only reason that he had not bled in these cases was that he not seen them early enough for bleeding to be of any avail. In cases of pulmonary oedema from cardiac and renal disease it is of less importance in comparison with a number of other remedies, and especially in the renal cases pilocarpine appears to give as good results as venesection. Regarding thoracentesis, he said that possibly the fatal cases reported may have occurred from the operation having been improperly performed, but that the operation could not be considered innocuous, as in some of the fatal cases it had been properly performed. He also said that most of the fatal cases of effusion were where the fluid was on the left side, and that thoracentesis should be performed where the effusion was large, causing dyspnoea, or where the fever pointed towards an empyema.

Dr. WELLINGTON said that he had bled in cases of pneumonia, but had not seen any benefit from it, and that he was surprised to hear that patients with pneumonia should, after venesection, be up and about in a few days, as he had always supposed pneumonia must run a staled course.

Dr. AYER said that he always carried a lancet in his pocket, and that he believed that bleeding freely was of great benefit in pneumonia, and that it was an error of the present day to leave these cases too much to themselves.

As regards the danger of the fluid becoming purulent after the operation of thoracentesis, Dr. DOE re-

marked that one would suppose such a result would certainly take place if air should enter the pleural cavity during the operation. He recalled to mind one occasion when, by mistake, air was injected into the pleural cavity when the fluid had been only partly withdrawn. Subsequent aspirations showed no ill effects from the accident, as the fluid continued to be serous in character.

DR. PORTER said : Mr. President, — As the discussion for the evening has closed, and the advantage of venesection has entered largely into it, I should like to ally myself with its advocates. Though I have had no experience in its employment in sthenic pneumonia I have used it a number of times in cases of cerebral congestion, which were marked by intense headache and flushed face. I call to mind two cases in women who were passing their "climacteric," in which venesection gave the greatest relief. The first was that of a lady not strong nor of plethoric habit, who had missed her "periods" for four months. I was called to her and found her complaining of intense headache, her face was flushed, her pulse full and slow, and the pupils uneven, the right apparently natural, and the left widely dilated. I bled her at once a number of ounces, and to the point of relief from her headache, her pupils became even, and she was entirely relieved of all symptoms. Her "period" came on a few days subsequently. The second case was also that of a lady at her "climacteric;" she was, however, naturally plethoric, with florid complexion. She had been suffering for a number of days from intense headache, could not tolerate the light, and the least noise disturbed her, so that she could not bear the presence of her husband or an only child in her room, though usually fond of having them about her. Her pulse at the wrist was weak though not rapid, and she complained that she could feel the pulsation in her head aggravated by the least exertion or excitement. I bled her freely, to her complete relief. A few months afterward I was sent for to repeat the venesection from which she had received so much benefit. I have also bled for intense persistent headache in young adults, and always to the satisfaction and great relief of the patient. I always carry a lancet.

DR. F. C. SHATTUCK said that seven years ago one of the physicians of St. Bartholomew's Hospital in London, in speaking to him of paracentesis thoracis, expressed the same fear in regard to the operation as is entertained by Dr. Lyman, namely, that a serous is often converted into a purulent effusion as a direct consequence of tapping. Dr. S. had himself, however, seen nothing in practice to lead him to adopt this view, provided, of course, that the instruments are clean.

And in this connection he alluded to the case of a young man whom he had sent from the out-patient room into the Massachusetts Hospital. There was a very large left effusion of some months' standing, and the cardiac impulse was to be seen and felt outside of the right nipple.

The fluid withdrawn at the first tapping was thin, but so purulent as to be perfectly opaque, and this fact led him to think that a permanent opening would prove necessary sooner or later. This fear was not, however, realized. Five or six times during some three months a moderate amount of fluid was withdrawn, and its character remained the same, neither more nor less purulent, throughout. When the patient was last seen the heart had returned to its normal position. It

would seem that if aspiration really involves great risk of favoring the development of pus in the pleural cavity, a fluid already so purulent as that in the case described would have become *pus pur et simple* between some of the repeated tapings.

DR. BLAKE, in opening the discussion, incidentally mentioned the skepticism in regard to drugs which comes with age and experience.

DR. SHATTUCK could not forbear the remark that among the younger members of the profession the change is rather from skepticism to belief than the reverse. Under the nihilistic teaching of the present day students graduate from the schools in profound disbelief as to the real value of any, or only half a dozen, drugs. For his own part, experience is teaching him that the list of active and useful drugs is far longer than he had at one time believed, and that the fault often lies, not in the drugs, but in our failure to make a proper application of them.

DR. WARREN spoke of the value of emetics in oedema of the lungs, and referred to a case already reported by him at a previous meeting, January 9, 1882; he also spoke of the case of a robust young man who was seized with pneumonia and where, from the extreme lividity and the full pulse, he had wished to bleed but was deterred by the advice of an older physician; the patient died, and Dr. Warren believed that his life might have been saved if he had been bled.

DR. S. CABOT reported the case of a clergyman who was attacked with pneumonia and in an hour and a half was livid and suffering from dyspnoea and pain in the chest. Dr. Cabot immediately bled him, and before the operation was over the patient felt relieved and the severe symptoms did not return; he thought that the course of the disease had actually been shortened by the venesection.

#### UTERINE FIBROID.

DR. F. H. DAVENPORT reported a case of sloughing fibroid, and showed the specimen.

The patient, forty-two years of age, was well until four years ago. Then had some increased pain and flow at the menstrual period, which were the only symptoms until last December. Then a week after the regular menstruation began to have severe labor-like pains, accompanied by profuse metrorrhagia. These symptoms lasted four weeks when the pains ceased, and the flowing was replaced by a watery discharge. In two weeks this began to be very offensive and profuse, and led her to apply at the Out-Patient Department of the Free Hospital for Women. A large mass the size of an orange was found filling the upper part of the vagina, the surface as exposed by the speculum breaking down, covered with brown shreddy material and secreting a foul-smelling discharge. The finger passed into the vagina showed the thinned-out cervix encircling the pedicle, and its character was clearly made out.

As the patient's general health had begun to deteriorate it was thought best to operate immediately, which was done by Dr. Baker. Under ether, the tumor was seized and drawn down by vulsellum forceps, and, with the finger as a guide, the pedicle divided with scissors. There was very little hemorrhage. As a precaution, a large tent of iron cotton was passed into the uterine cavity, and the vagina was plugged with cotton.

The dressings were removed in forty-eight hours,

and the vagina was washed out with carbolized injections twice daily. The patient made an uninterrupted recovery.

The interesting points in the case were the mild character of the symptoms until the expulsion of the tumor, slight dysmenorrhœa, and menorrhagia, and the quick expulsion of the growth.

#### PERIPLEURITIC ABSCESS.

DR. LYMAN read the following paper:—

James McDonough, a lamplighter, aged 30, entered the City Hospital October 24, 1881, with a supposed pleural effusion. The following notes of the case are mostly from the hospital records, but as these records were not complete, I have recently (February 25th) been able to supplement them by such additions as the patient's memory would supply.

His vocation necessitates a daily walk of twelve miles. In addition to this he is occupied during the day in loading heavy teams, a labor involving severe and long-continued lifting. He is of a healthy family, rugged, and was never sick until September 19th, about five weeks before entrance, at which time, without any especial exposure or any other known cause, he was attacked with symptoms, as was supposed, of pleuritis, namely, pain in the left side in the axillary line, chilliness, dyspnoea, cough and vomiting, followed by night sweats and general weakness.

Physical examination October 24th revealed flatness over the lower left back, with almost entire absence of respiration, diminished vocal fremitus and bronchophony. Three days later, the 27th, he began to complain of pain in his back, which interfered with his movements and prevented sleep. Upon examination a doubtful, deep-seated fullness was observable (see diagram) below the ribs, close to the spine, some three or four inches in diameter, and tender on firm pressure. He thought he was obliged to evacuate the bladder more frequently at night. No other renal symptoms; urine free from albumen or sediment. Specific gravity 1026.

November 1st. The swelling having become decidedly more prominent, an exploratory deep incision was made and an ounce of thick, greenish, inodorous pus evacuated; the probe subsequently passing upward and anteriorly four inches.

November 5th. There has been an abundant and continuous discharge of bloody, inoffensive pus from the wound, accompanied for the past three nights by profuse sweats.

The discharge gradually diminished, and on the 10th had ceased entirely, with closure of the wound. There being no sweating or pain remaining and no signs of reëfilling, the opening was not meddled with. The line of dullness on percussion of the chest was found to have descended one and a half inches during the ten days. On the 22d the respiration was good throughout the whole left lung, although there was still comparative dullness at the base beginning two and one half inches below the angle of the scapula. No signs of the abscess remaining, he was discharged.

Three months later, February 25th, I had the curiosity to hunt up the patient and found that the remaining dullness had entirely disappeared and he was performing his usual work without pain or any embar-

assment of respiration, and feeling as vigorous as ever.

The only point of especial interest and justifying a report of the case is as to the origin of the abscess. Was it a case of empyema, the pus escaping from the pleural cavity and finding its way below the diaphragm, or was it primarily a peripleuritic abscess burrowing its way into the latus and by its presence giving rise to a secondary pleuritis or to the symptoms simulating that affection?

For our present purpose we may exclude all considerations of organic pulmonary disease, as well as caries

/// = Flatness - aegophony - absence of respiration and of vocal fremitus  
 T = Tumor found on 27<sup>th</sup> Oct. by palpation and inspection  
 X, point where abscess

or fracture of the ribs, as there was evidently no such complication.

The fact is well established of the occasional bursting of an empyema into the lungs or the mediastinum, or its spontaneous exit between the ribs—and so, also, rare cases are met with of actual perforation of the diaphragm. Andral<sup>1</sup> gives such a case verified by autopsy. Fraentzel<sup>2</sup> also speaks of an ulcerative process through the costal pleura, the pus either perforating the intercostal muscles or making its way down beneath the ribs until, getting below the diaphragm, it may migrate almost anywhere.

For an interesting case occurring in Dr. Minot's service I am indebted to Dr. Rotch. A lad of sixteen with empyema had a large quantity of pus removed by aspiration and incision. A month later, after some intermediate abdominal pain and tenderness, two quarts of sero-purulent fluid were aspirated from near the umbilicus, and subsequently large amounts were discharged from both openings for nearly two months, the boy ultimately recovering. Andral gives still another case (page 510) where the pus following the psoas down behind appeared in enormous quantity below the diaphragm. In the *Gazette des Hôpitaux*, May, 1870

<sup>1</sup> Clinique Médicale, vol. iv., page 471.

<sup>2</sup> Ziemssen, vol. iv., page 620.

(page 237), Courbon relates a case of empyema which occurred in the hospital at Tours. The patient was pregnant. The abscess pointed, as in the case which I report, below the ribs and near the spine. Owing to aortic impulse it was supposed to be aneurism, but a large amount of matter escaped externally by a spontaneous opening and the patient recovered.

In the *Medical and Surgical Journal* of November, 1877, page 587, Dr. Fitz calls attention to "peripleuritis, a suppurative inflammation of the fibrous tissue beneath the costal pleura which arises independently of traumatic causes or a preceding pleurisy, and first noted by Wunderlich in 1861 and subsequently by Billroth, Bartels, and Riegel."

In the *Archives Générales* 1865, vol. i., pages 403, 565, I find an exhaustive article by Leplat, agrégé at the Val de Grace, upon these peripleuritic abscesses and their relation to antecedent pleuritis. In opposition to Wunderlich, Leplat argues that they are always (excluding, of course, carious or traumatic cases) secondary to pleuro-pneumonia or pleuritis; and from the details which he gives (page 570) of the cases of Wunderlich and Billroth, it seems at least probable that their cases were also secondary, and not, as claimed by them, of independent origin. I think, also, that it may be said of Bartels' cases as reported by Dr. Knight (*Boston Medical and Surgical Journal*, October, 1875, page 437), that it is not clear that the abscess was not due to caries of the rib, instead of being a primary suppurative inflammation of the subpleural fibrous tissues.

In the case which I report the diagnosis clearly lies between primary pleuritis followed by empyema on the one hand and primary peripleuritic abscess, as described by Wunderlich with either simple compression and displacement of the lung or secondary pleuritis, on the other.

The probabilities seem to me to be in favor of the peripleuritic origin of the abscess. The patient was an intelligent man and able to answer as to his antecedents. He was young, exceptionally well nourished, of vigorous muscular development, never sick before, with no history of pulmonary diathesis or hereditary predisposition to it, and engaged in an occupation requiring heavy lifting and straining. He gives no history of any initiatory rigor or of any definite cause in unusual exposure. There was no albumen in his urine. The pus obtained, though not tested for its specific gravity, was thicker than is usual in empyema. The line of dullness in the chest upon percussion fell rapidly when the abscess was evacuated. In ten days the discharge ceased entirely and there was no recurrence of it, and a fortnight later no sign remained of pleuritic or pulmonary irritation, with the exception of a limited dullness readily accounted for by adematous thickening or unabsorbed lymph. Three months later he reports himself as well as ever, walking fast for two hours morning and evening, often, indeed, running a good deal when delayed, and in the intervals of the day doing heavy work, all without pain in his side or any embarrassment of respiration.

Dr. BOWDITCH said that the main point to be insisted upon in these cases, as well as in cases of perinephritic abscess, was that a free opening should be made at once, and he cited a case where, from postponing the operation, the patient was now incurable and had an intestinal fistula opening into the cavity of the abscess.

## Recent Literature.

*Percussion Outlines.* By E. G. CUTLER, M. D., Assistant in Pathological Anatomy, Harvard Medical School, etc.; and G. M. GARLAND, M. D., Assistant in Clinical Medicine, Harvard Medical School, etc. Boston: Houghton, Mifflin and Company.

We are informed in the preface of this valuable little work that it is intended to teach students the anatomical position of the thoracic and abdominal viscera, chiefly with reference to the normal condition, without a full description of the abnormal deviations. This study of external or regional anatomy is one of great interest and importance clinically, and it is also one which in most medical courses the student is expected to pick up for himself without much systematic or accurate instruction. The book under consideration is filled with data drawn from the best sources and verified by the careful researches of the authors, supplemented also by their own original observations, for which they have had exceptionally good opportunities. It may be accepted as a strictly accurate and concise authority with regard to the boundaries of the lungs, heart, diaphragm, and pleura, also of the liver, stomach, bladder, kidneys, and other abdominal organs. The pathological conditions within the lungs, pleura, and pericardium have been the subject of special study by the authors, whose remarks on these points are prompted by experience at the bedside and autopsy table.

The diagnosis of peritoneal effusions, uterine and ovarian tumors, is briefly discussed, and at the end are nine excellent reproductions of Weil's plates, alone worth the price of the volume, which in style and appearance is unexceptionable.

However valuable metres and cubic centimetres may be to science, they would be more satisfactory to many physicians still in the habit of thinking in the old-fashioned measures if they were translated parenthetically into inches and fluid ounces.

*The Prevention of Stricture and of Prostatic Obstruction.* By REGINALD HARRISON, F. R. C. S. London: J. and A. Churchill. 1881. 28 pages.

Every one familiar with Mr. Harrison's *Surgical Diseases of the Urinary Organs* will be sure to turn with interest to any article on the same subject which bears his name. This little book is composed of two essays, of which the first, or at least its substance, on the Prevention of Stricture, was published some months ago in the *Lancet*. It proposes the treatment of long-standing gonorrhoea and gleet by a system of irrigation which appeals strongly to one's common sense. A little experience in its use shows that extreme care must be exercised in the choice of subjects, as the irritation caused by its too early employment brings on an exacerbation of the trouble. Its exact value has yet to be determined. The second essay treats of the Prevention of Prostatic Obstruction, and is first published in its present form. It is exceedingly interesting, and gives us reason to believe that early treatment may ward off the evils of an enlarged prostate, and perhaps prevent their increase even after some slight degree of obstruction has already taken place.

# Medical and Surgical Journal.

THURSDAY, MARCH 16, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

## THE PRIZES FOR ESSAYS ON THE PROBABILITIES OF A CURE FOR MALIGNANT DISEASE.

REFERENCE to our advertising columns will show our readers the decision of the gentlemen selected to judge of the merits of the essays on the radical cure of malignant disease, presented in response to the offer of prizes published to the medical profession in November last, and will give them the details of a new announcement. We feel assured that the decision not to award a prize is as disappointing to the gentleman who made the proposal as it can possibly be to any one of the three unsuccessful writers. It is not worth while to speculate at any length concerning the cause of the lack of interest manifested in the offer: the matter of practical indifference in prize-essay writing in this country has been already commented on by us, as well as by other American medical journals. The fact has been attributed by a contemporary to the "comparative barrenness of American researches in the field of medical science;" but the particular offer which is the subject of this article called not so much for the result of original scientific research, as for practical suggestions evolved from thought upon work already done, and experiences already noted. A record of such reflections America ought to be as well able to furnish as any other country.

Some criticism has been made of the brevity of the time allowed for the preparation of the essays. Whatever force the objection may properly have, the criticism will not be applicable to the period of time given in the new announcement: twenty months is surely a sufficiently long period in which to prepare an essay not necessarily involving original histological investigations.

As regards also the value of the new prize, it will be conceded that the amount is really generous. There are, we believe, about half a dozen prizes offered altogether in the three large Eastern medical centres of this country, New York, Philadelphia, and Boston, the sum total of which does not exceed, if it even reaches, one thousand dollars annually. In the recently published list of prizes proposed for the year 1882, by the French Academy of Medicine, there are fourteen different sums. The largest amount is \$5000; there are two prizes of \$1000 each, and one of \$600; while the remaining ten are about equally divided between prizes of \$250, \$300, and \$400. The total amount thus offered is something over \$10,000, mak-

ing the average amount of each prize a little over \$700. It will therefore be a marvel to us if the generous award of one thousand dollars proposed in the new announcement does not elicit an essay quite worthy of the bestowal of such a prize. And it ought not to be said that America shows signs of less activity than other countries in the effort to advance the cause of practical medical science. Twice in later years has the Boylston prize been borne off by English writers; and we may add that, in the case of the essays of which we write, there was external evidence of foreign competition, and to quite a disproportionate degree.

## VENESECTION.

THE report, which will be found on another page, of a discussion upon the treatment of pneumonia, is only another evidence of the constant revolution going on in the methods of medical treatment.

Real medical science advances, with more or less of rapidity to be sure, but always gaining something from decade to decade, every new discovery whether physiological, pathological, anatomical, chemical, or microscopical, giving a firmer foothold for the progressive elevation of art into science, and so permitting the student of preventive medicine to avail himself of hygienic laws more and more positive and demonstrable; but notwithstanding this encouraging outlook, the general practitioner feels constantly how much is yet to be attained, and must still avail himself, to a certain extent, of procedures which are taught him by experienced art rather than by exact science.

It is only those who have passed middle age who can adequately realize how continuous is the revolution of the wheel, though not always in the same plane. As beginners they heard the same story of previous professional progress, though certainly to a less marvelous degree, and in the pride of the scientific vista opening to them fancied that they were greatly wiser than their predecessors. So, doubtless, will their successors in another third or half century turn and say to the generation following, we also have learned a few things, but in the marvelous whirl of scientific progress and discovery of which we have been favored witnesses we have forgotten or neglected many which possibly might be remembered to advantage.

It is only forty years or so ago that venesection, in acute diseases, was the solid shot always first fired to sink the enemy, to be actively followed up by grape and canister at close quarters. Every student was expected to be skillful with the lancet if nothing else, and in his professional quandaries, like the frishman with his shillalah, wherever he saw a head he hit it unhesitatingly. Nowadays there are men well advanced in years who have never performed this bit of minor surgery, and one such, an experienced practitioner, avowed in fact that he had never even *seen* a man bled! We ourselves well remember a consultation with three medical gentlemen, but a few years since, where venesection was decided to be necessary in an urgent case of eclampsia — one of them only had the neces-

sary lancet, and even that, though carried many years, had never before been baptized.

The question may well occur to thoughtful minds, are we not in danger, while pursuing so ardently the scientific aspects of our calling, of overlooking or slighting some remedial measures which experience in the art has demonstrated to our predecessors as certainly beneficial? The scientist may certainly fail of success without the assistance of the artisan who can sometimes achieve results by rude processes which the former finds to be impossible of present mathematical demonstration. We know that the loss of blood, either in its quality or its quantity, tends to fatal results, and for physiological reasons which can be demonstrated now as never by our fathers: but until science can give us a substitute, there are cases in which art must step in with its ruder process and put off the fatal day until Dame Nature can have at least a chance to try her hand.

Such at least seemed to be the opinion of some of the gentlemen, as given in the discussion which we publish, — a discussion which was intended to cover much more generally the treatment of pneumonia, but which for lack of time was confined chiefly to venesection as one of the lost arts. Moreover, its application was limited emphatically to that smaller number of cases strictly sthenic, the more common asthenic cases not entering into the question.

The sentiment, so far as expressed, was pretty decided that there were a certain number of these sthenic cases occurring in strong and vigorous subjects, almost apoplectic, fondroyantes in character, where temporizing, expectant treatment, under the idea that the disease must run its definite course, would surely run that course too speedily for the sufferer. As with superheated steam, the valves must be opened at times, or the boiler gives way before you can lower the fire. In other words, let off enough to relieve the tension, and give the patient a chance for the restorative processes of nature, aided by good nursing and such expectancy as circumstances might afterward indicate.

It is well worth while in medicine, as in the other pursuits of life, for us to show occasionally the courage of our convictions, and, regardless of Mrs. Grundy, do the best thing we can under the circumstances, though it may not be the best we could wish.

There is little danger of venesection being too much practiced in these days. There is great danger that here and there a valuable life may be lost from timidity, — the want of prompt and decisive action in this direction. Every practitioner knows of such cases, while many of those present were able to speak of the prompt and gratifying results of this operation in cases otherwise apparently hopeless.
